

Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Piano, Electric: Davis (*Expir.*), 826
Planing Machines, Electrically-driven: Vickers, Sons & Maxim, 678
Potentiometer for A.-C. Measurements: Drysdale, 134, 357
Power-factor, Regulation of: B.T.-H. Co., 942
Pressure Regulation: Felten & Guilleaume-Lahmeyer Co., 21
Primary Cell: Heintz, 594; Hunte (*Oppos.*), 859; Spiliotopol, 859
Protection of Cables: Allgemeine Elektricitats Ges., 859
Protection of Generators: Siemens Bros. Dynamo Works, 806
Pulley Block, Electric: The Electric Pulley Block Co., 1070
Pump, Electrically-driven: Mallinson (Suppt.), xviii
Pumping Plant, Portable: Stevens, 994

Railway Signalling:—B.T.-H. Co., 924; Brown, 888; Pryce and Ferreira (*Expir.*), 272; Siemens Bros. & Co., 311; Sykes (*Expir.*), 974, 902; Tyer (*Expir.*), 974; Union Switch & Signal Co. (*Oppos.*), 452, 1014; Westinghouse Brake Co. (*Expir.*), 1086; Winter (*Expir.*), 311
Rail Joint: Flett and Dick, Kerr & Co. (*Expir.*), 974
Relays: Allgemeine Elektricitäts Ges., 544, 924; Statter, 942; Timar and Zeigler, 750
Resistance, Adjustable Carbon: Martin (*Amend.*), 859, 1014
Resistance-Units: B.T.-H. Co., 1104; Cooper and Sharp, 714; Siemens-Schuckertwerke Ges., 622; Voigt and Hoeffner (*Expir.*), 357, 568; West, 1104
Rolling Mills, Driving of: B.T.-H. Co., 902; Brown, Boveri & Cie., 272; Electric Construction Co., and Buchanan, 594; Siemens Bros. Dynamo Works, Ablett, and Crowe, 622; Soc. Anon. D'Ougrée-Marihaye, 1014
Rotors, Short-circuited: Lancashire Dynamo & Motor Co., 678

Sheathing, Metal, of Insulated Wires: Rawlings and others, 942
Ships, Electrical Propulsion of: Durtnall, 1014
Signalling Lamp: Shilston, 642
Sparking Plugs: Renault, 942
Speed Indicators: Hartmann & Braun A.-G., 189
Split-pole Converter: B.T.-H. Co., and Whitaker, 1070
Steering Gear, Marine: Parker-Haigh, 974
Storage Battery Plates: Accumulatoren-Fabrik A.-G., 854; Faure & King (*Expir.*), 70; Fiedler, 519; Nya Ackumulator Aktiebolaget Jungner, 750; Rhodin (*Expir.*), 406
Storage Battery Plate Separators: Van Raden & Co., 678
Storage Battery Sub-stations on A.-C. Systems: A. M. Taylor, 174
Street Lighting: Simmance and Abady (*Restor.*), 174
Supporting Flexible Conductors: Laurie, 1070
Surface Contact Tramway System: Mordey, 950; S.P. Syndicate and Sayers, 94
Switch, Battery Charging: Nalder Bros. & Thompson, 974
Switch, Bedside: Drake & Gorham, 189
Switch Case: Horrocks and Lett, 788
Switch Change-over: Chloride Electrical Storage Co., Ltd., and Imbery, 1030
Switch Contacts: Siemens Bros. Dynamo Works, 544
Switch, Electromagnetic: Venner, 678
Switch, Knife: Verity's, Ltd., 788
Switch, Limit: Nalder Bros. & Thompson, Handcock, and Dykes, 430; Wilkinson, 974
Switch for Advertising Device: Lüling, 174
Switch for Power Circuits: Cooper and Sharp, 678
Switch, Thermal: Kelly (*Amend.*), 70; Sweetser, 994
Switch, "Twinob" Motor-starting: Lundberg, 338
Switch-fuses: Hope, 406; Kennedy-McGregor and Mountford, 139
Switchgear, Iron-clad, Hope, 924
Switchgear, H.-T.: Bertram Thomas, 594; Field and Ferranti, Ltd., 1014; Peyrusson, 519
Switchgear for Coal-cutters: Fisher and others, (Suppt.) xiv

Tantalum, Production of: Siemens & Halske Akt.-Ges., 1104
Telegraph Transmitter, Keyboard: World Flash Co., U.S.A. (*Expir.*), 139
Telegraphic Apparatus: Buckingham (*Expir.*), 727; Burry (*Expir.*), 272; Dearlove (*Expir.*), 430; Higgins (*Expir.*), 357; Mercadier and Pierquin (*Expir.*), 950; Steljes (*Expir.*), 727; Taylor and Dearlove (*Expir.*), 544
Telephone Calls, Recording: Sinclair and Aitken, 950
Telephone Exchange Connections: Siemens Bros. & Co., 994
Telephone Magneto: Buschelberger, 139
Telephone Exchange Indicating Lamps: Western Electric Co. (*Expir.*), 544
Terminals Ridgway and Brunt, 121
Thermal Storage: Morison (*Oppos.*), 430
Third-Rail Protection: Essex Co., U.S.A., 568; Merz and Redman, 463
Time Limit Device: Electric & Ordnance Accessories Co., 648, 974
Tool for Removing Lamp-shade Rings: Broadbent, 1052
Train Lighting: Moskowitz and others (*Expir.*), 370, 642; Preston & Gill (*Expir.*), 70
Tramcar Life-guard: Timbrell and Gabriel (*Oppos.*), 311, 750
Tramcar Trolley-wheel: Bennet and others, 714; Holmes, 924; Shepherd and Ullery, 94; Wermann, 463

Digitized by Google

PATENTS (*continued*).

Tramway Conduit System: Angle, 430
Tramway Overhead Construction: Ormston and Charlton, 888
Tramway Points, Electromagnetic Operation of: Tierney and Malone, 463
Tramway Rails: Briggs (*Amend.*), 311, 463; Mountain & Gibson, and Pringle, 622
Transformer for Vapour Lamps: Conrad, 370
Transformer, D.C. Rotary: Akt.-Ges. Brown, Boveri & Cie, 662; Schäffer, 121
Transformer Switches, Automatic: Sunderland and Pullinger, 678, 727
Trolley Wire Cut-out: Barraclough, 694
Tungsten Compound: Harrison and Dorman (*Surrend.*), 452
Tungsten-Nickel Alloy: Siemens & Halske A.-G., 406; (*Oppos.*), 594, 834 (*see also* Metal Filaments)

Variable Speed Polyphase Motor: Mavor & Coulson (*Amend.*), 215, 452
Ventilation of Laminated Cores: Low, 174
Ventilation of Machines: Akt.-Ges. Brown, Boveri & Cie., 452; Chitty (*Restor.*), 140; Hall, 189; Ingleby, 406
Ventilation of Ships: Keith, 1104
Vulcanising Apparatus: Allman and Leeson (*Oppos.*), 215, 642

Wireless Telegraphy: Eisenstein, 94, 694; Fessenden, 1014; Lepel, 1086, 1104; Marconi's Wireless Telegraph Co. (*Oppos.*), 642, 806, 826
Wireless Telephony: Blondel (*Restor. refus.*), 678
Wiring Conduit: Evans, 463; Lamkin and Nunwick, 1030; Strode, 1030
Wiring Systems: Highfield, 1070; Siemens Bros. & Co., 888

Displayed Advertisements, *Tuesday first post.*

Corrections in Standing Advertisements, *Monday first post.*

All letters to be addressed to "Electrical Engineering," at the Editorial and Publishing Offices: 203-206, Temple Chambers, London, E.C.
Telegrams: "Circling, London." Telephone No.: 5509 Holborn

Cheques to be made payable to The Kilowatt Publishing Co., Ltd., and to be crossed London and Westminster Bank (Temple Bar Branch).

BINDING "ELECTRICAL ENGINEERING."—Vol. IV. of "Electrical Engineering" (July—December, 1908) closed with our last issue. An index for the volume is now ready, and copies may be ordered from any newsagent or bookseller at the price of 1d. each (or post free, 1½d). Binding Cases, including index, are also ready, price 2s. each, post free 2s. 4d. Readers can have their volumes bound by their own bookseller; or they may send their numbers to us, carriage paid (with the reader's name and address), and a remittance of 4s. 6d. under separate cover. The volumes will then be bound and returned carriage paid to any address in the United Kingdom, or carriage forward to the Colonies or abroad.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

In an article by Mr. A. G. Ellis, the relative costs of copper and iron in alternating and continuous-current generators are considered, and it is shown that, whereas the copper costs constitute some 55 per cent. of the total cost of effective material in the case of continuous-current designs, this figure falls to less than 35 per cent. in the case of alternating-current designs. The preponderance of copper in the former case is explained as being due to commutation restrictions. The effect of these considerations on the relative weights and costs of alternating- and continuous-current generators for various ranges of speed and output is then shown by a number of curves, and finally some curves are given which show that at high speeds C.C. machines weigh less but cost more per kilowatt than A.C. machines. (Page 5.)

An article by "A Pessimistic Correspondent," reviews the conditions under which power companies are working. He points out that the companies have scattered districts owing to their not being allowed to enter the large municipal areas, and that there have been other causes to make the capital expenditure high. Taking an imaginary case of a company that has spent £600,000, and has 8,000 kw. installed in its power-house, and generates 21,024,000 units per annum at a plant load factor of 40 per cent., he calculates that the capital cost and establishment charges per unit sold will be 0·527d., and the works costs 0·25d., making a total of 0·777d. per unit, and in order to pay 5 per cent. dividend the units must be sold at 1·201d., a price which would be prohibitive. We comment on this article in an editorial note. (Pages 3 and 7.)

Two patents have been granted recently to Mr. Edison for improvements in the well-known alkaline storage-cell. One of these relates to the preparation of the thin films of nickel or cobalt used as an addition to the active material, and the other covers a method of constructing a plate which consists of a frame or grid in which are fixed the perforated nickel pockets containing the active material. The method permits of the ready substitution of a new pocket for a damaged one. (Page 8.)

THE following books are reviewed in this issue:—"Outlines of Electrical Engineering," by H. H. Simmons; "The Practical Electrician's Pocket-Book for 1909." (Page 9.)

SOME trouble was caused last week on the L.C.C. tramway system by the methods employed by the road authorities to deal with the snow. (Page 10.)

AN interesting feature of the geared single-phase motors now under construction for the new motor-cars of the New York, New Haven, and Hartford Railway is the provision for the whole of the weight of motor and gear to be spring-borne. (Page 10.)

THE report of Mr. C. E. Stromeyer to the Manchester Steam Users' Association contains results of a number of tests on boiler plate materials, and a discussion of the causes of water hammer. (Page 10.)

DR. J. TEICHMÜLLER has recently carried out a number of experiments on the influence of the magnetic controlling field on the regulation of arc lamps with converging carbons. He disagrees with the view that the feeding of the carbons is accelerated by the use of a magnet above the arc, because the arc approaches the magnet and is lengthened out as the carbons burn, and considers that the true reason why a magnetic field across the arc improves the regulation is that it steadies the arc, keeping it at the carbon tips, and preventing sudden variations in its length or resistance due to it leaving the impregnated cores. The experiments also indicate that a homogeneous field across the arc is better than a field increasing towards the top of the economiser. (Page 11.)

MR. E. A. Ashcroft's Paper on the influence of electricity on the electrolytic and electrothermal industries was chiefly devoted to an examination of the financial aspect of water-power development, and contained examples of estimates based on supply at £2 10s. per kw. year. (Page 11.)

ONE of the suggested methods of improving the load factor of small generating stations is the supply during certain hours of the day and night only to works in which electrochemical, refrigerating, or other processes capable of intermittent working are carried on. It is generally found that intermittent working does not pay, but a new system of ice-making, capable of producing ice very rapidly, has been introduced into America, which, it is claimed, may be worked intermittently with good results. (Page 13.)

THE question of standardisation of overhead line equipment for electric railways has been considered by a Committee of the American Railway Association. In their report, they review existing practice, but consider it inadvisable to impose definite limitations at present. (Page 14.)

IN a winding plant erected by Messrs. Brown, Boveri and Co. in a German mine, the peaks of the load are met by supplying high-pressure steam to the expansion stages of the turbine driving the set from which the supply is taken. A second generator on the same shaft as that supplying the winding motor supplies the ordinary power-load of the mine. No flywheel set is used. (Page 14.)

A RECENT Paper read in America described some features of the Fessenden wireless telephone system, which employs an inductor alternator of very high frequency. With this apparatus conversation has been carried on over a distance of 200 miles. (Page 13.)

A COMBINED lighting and traction station in which 60-cycle alternators are driven in parallel by gas engines working on producer gas obtained from bituminous fuel, recently put into operation in a small town in America, is described. (Page 15.)

NEGOTIATIONS are being carried on with reference to a lease of the Acton electricity undertaking by the Metropolitan Electric Supply Co.—Mr. J. B. Hamilton's report upon the Bournemouth Corporation tramway undertaking suggests a reorganisation of the staff and the running of cars on Sunday.—Messrs. R. W. Blackwell & Co. have issued a writ against the Derby Corporation in respect of penalties amounting to £1,573 deducted from their account for tramway construction.—It is proposed that a local company should be formed in Falmouth for working a system of trackless trolley omnibuses.—The total cost of the Pye Nest (Halifax) tramway disaster is now put at £11,090.—It is stated that the cost of clearing the tramway tracks in Liverpool in connection with the recent fall of snow was £600.—The St. Pancras Borough Council has put into operation a new 2,800 kw. Willans—Dick-Kerr turbo-alternator and a 1,400 kw. Bruce Peebles motor-converter.—A suggestion has been put before the Sunderland Tramways Committee by the Sunderland District Tramways Co. for mutual running powers. (Page 16.)

TENDERS are invited by the Hammersmith Borough Council for a 2,000 kw. turbo-alternator. Sanction has been given to the Wimbledon Council to borrow £6,000 for electrical purposes. An application is to be made for a loan of £4,000 by the Worcester Corporation. A scheme of street arc lighting has been adopted by the Finchley Council. (Page 18.)

THE accounts of the Sunderland District Tramways Co. for the year ended March 31st, 1908, show a loss of £1,467, bringing the loss up to date to £13,823. The directors of the London United Tramways Co. recommend a payment on account of the 5 per cent. cumulative preference shares at the rate of 2½ per cent. per annum for the half-year to December 31st, making 3¾ per cent. for the year. There has been a somewhat disappointing increase in the traffic receipts. (Page 19.)

AMONG the specifications published by the Patent Office on Thursday last is one by F. Harrison relating to spring supports for metal filaments. A specification by W. J. Davy describes several of the improvements which have been incorporated in the latest pattern of the Davy openflame arc lamp, and another by Felten & Guilleaume Lahmeyerwerke Akt.-Ges. relates to a method of automatically regulating the pressure of dynamos by connecting an over-compounded machine in parallel with the machine to be regulated. The Allegemeine Elektricitäts-Ges. have two patents referring to arc lamps; the first is for a means of extinguishing the arc when the carbons have burnt down to the shortest permissible length, and the second is for an arrangement of the converging carbons of flame-arc lamps, which facilitates regulation, and enables a cover to be fixed over the holes in the economiser. A specification by O. Schulze relates to a method of compensating for temperature in meters with Foucault brakes, and another by E. Schattner and R. Amberton refers to the electrolytic prepayment meter previously described in these columns. A process for the manufacture of tungsten filaments in which a ductile alloy of tungsten and nickel is first produced, is described in a specification by Siemens & Halske Akt.-Ges. Among the patents expiring during the current week is one by R. Belfield for a lightning arrester. Short abstracts of the above are given in our Patent Record. (Page 21.)

A NEW Bill, providing for the Government control of water-power undertakings, has received the sanction of the Swiss people. (Page 23.)

A SHORT article describes a new form of brush gear which has several advantages. (Page 23.)

SOME details of important colliery and other power installations installed during 1908 are given. (Page 24.)

WE give the complete list of applications to the Board of Trade for electric lighting provisional orders for 1909. (Page 24.)

Digitized by Google

WE publish an article this week, contributed by a well-known member of the electrical industry, whose name, however, we are not permitted to disclose, in which a particularly unfavourable estimate is made of the prospects of electric power companies in this country. The writer points out the effect of the restrictions under which these companies have had to work. They have to earn dividends upon a capital that has been much inflated by the cost of parliamentary procedure and the difficulty of raising money at the outset; they are prohibited from developing their business within the boundaries of the largest towns and cities in which municipal electricity works are in existence; and, lastly, the exclusion of these areas increases the cost of the transmission and distributing lines, which have to be extended to the less populous parts of the companies' districts, so that a greater length of main is required per consumer. That these difficulties are present cannot unfortunately be denied, and practically every power company is doing what it can to come to terms with local authorities, both for permission to supply power in their areas, and also to supply the local authority itself "in bulk"; moreover, the use of overhead lines is being resorted to wherever practicable, when the necessary consents are obtained. Our correspondent is, however, so dissatisfied with the results of these endeavours, that he puts forward estimates to show that under present conditions the power company is saddled with a task which it cannot in any way accomplish, and that its shareholders will have to wait until the Greek Kalends for a modest five per cent. dividend. These estimates will have to be corrected considerably before they can be accepted as typical of the actual state of affairs, and we publish the article in the hope that some of our readers whose interest in the matter is great will overhaul our correspondent's figures, and give us an indication that the future is by no means so black as he has painted it. He has assumed in the first instance the enormous capital of £600,000 for a system with a plant capacity of 8,000 kw., that is to say, £75 per kw. This would be a large figure for a lighting station of medium size supplying a number of small consumers with a lighting load factor, and it is an absurdly high one to represent the position of a power company after its preliminary stages of development have been passed through. The cost of the power-house with its larger units is less per kw., the low tension network is practically dispensed with, and the cost of services and meters per kw. is enormously less owing to the larger demand of each consumer. The preliminary expenses can surely not have been great enough to set off this saving. On large capital, our correspondent takes five per cent. as an annual charge for depreciation, that is to say, he takes depreciation not only on the machinery and plant and cost of erection, but also on the very large sum he has assumed to have been expended on obtaining parliamentary powers and capital, or, in other words, the goodwill of the business. Adding estimated figures for establishment charges and works costs, and a further allowance for paying a five per cent. dividend, he arrives at a grand total of 1·204d. per unit for an output estimated on the basis of a reasonable plant load factor. But as 0·45d. of this represents the capital charges on the basis of five per cent. depreciation on £75 per kw., and as the five per cent. dividend is also taken on this capital, our correspondent's conclusions can hardly be accepted. Nevertheless, the article is worthy of careful study by those interested in power stations, for it is evident that the profits to be derived from some of these schemes are not so high as some of the promoters have thought, and that the tendency is towards charging a lower price for power than is justifiable by cautious financial considerations.

COMPARATIVELY little has been published on the principles underlying the action of the flame-arc lamp, as, naturally, the results of the extensive research work which has been carried out by those commercially interested in these lamps are not widely circulated. This is particularly the case with regard to the magnetic control of the arc in lamps with converging carbons. At the very beginning, it was realised that, owing to the better distribution of light and the lesser tendency for the formation of slag on the carbon tips, the arrangement of converging carbons was superior to the axial position when chemically impregnated carbons were used, but trouble was experienced with this arrangement until the arc was put under the influence of a magnetic field similar to, but stronger than, the field produced by the arc and carbons themselves. This field has many functions, but, although practically all types of flame arc lamps on the market are provided with such a field, the exact nature of its influence seems to be very uncertain. If the arc current is less than about 10 amperes, and the angle between the carbons wide, an additional field is required to prevent the arc running up the carbons under the influence of the hot-air currents, although a flame-arc with converging carbons was shown working at the recent exhibition at Manchester without any additional field whatever. Again, it is sometimes thought that a magnet is necessary to lengthen the arc artificially, and thus operate the feeding mechanism through the medium of the shunt coil, when the carbons have burnt down to the roof of the economiser. In a recent article by Dr. Teichmüller, of Karlsruhe, an abstract of which we publish in this issue, this latter view is asserted to be incorrect. The most important function of the additional field is, he says, to keep the arc at the cores of the carbons in order to prevent sudden variations in its resistance. Other interesting points are raised in this article, one of which is the best form for the field. Some makers provide very elaborate saturated magnetic systems with special projecting poles to lead the leakage flux across the arc, while others wind a series of coil of a few turns on any convenient portion of the iron framework of the lamp in an apparently haphazard way. Again, the field is in some cases nearly all above the arc, in some it is below the arc, and in others a more or less homogeneous field is provided across the arc, extending both above and below, which, according to Dr. Teichmüller, has the best effect. With all these different arrangements before us, it is difficult to deduce the principle underlying the evidently beneficial effect of the additional field, but as the different makers will doubtless continue to modify their lamps in the light of new experience, some unity of design may eventually be revealed.

AT the close of the deliberations of the International Conference on electrical units and standards there was naturally some speculation as to the actions which the various Governments concerned would take, in view of the very opposed views held by some of the delegates attending the conference. The French and American representatives, in particular, were at variance with the majority of the others, as shown by the numerous counter-proposals which emanated from both these sources. There is reason to believe that the French Government will not be prepared to act upon the decision of the Conference, which they regard as likely to become a dead letter. Certainly, their delegates regarded as erroneous the values of the units as voted by the majority of diplomatic representatives, who, in the plenary sitting of the Conference, overthrew the recommendation of their own Technical Committee. The French delegates declare it to be illogical to agree to a definition of a unit, and then to agree to a second definition of the same unit that is different from the first. At the Conference the Italian delegate did not mince matters, but, with more frankness than diplomacy, spoke of the proposal to fix the electrochemical value of the ampere at an arbitrary value as "a sort of scientific lie." Italy is, therefore, not likely to fall in with the decisions that its representative so emphatically denounced. From the frame of mind of the American delegates on their return home we look forward to similar news from the other side of the Atlantic. It is a pity that, after so much trouble has been taken, a nearer approach to unanimity could not have been arrived at, but in the light of the present situation it is clear that our own Government should pause to consider well before giving effect to legislation which, in view of these dissensions, would be bound to become a dead letter. We do not want a repetition of the mistake made with the so-called "legal" ohm of 1884, and on the present occasion it must be remembered that the conclusions of the Conference have not by any means been received with universal approbation in British electrical circles. Any attempt to rush a new Order in Council through the Board of Trade would be disastrous.

IN our last issue we commented on a statement made by the United States Consul at Glasgow, with regard to the meaning of the now famous revocation clause of the Patents Act of 1907. He asserted that "the generally accepted reading" of the clause in question was that, instead of manufacturing a patented article in this country in its entirety, the American patentee might send over the parts of the machine and merely assemble them here, without incurring the risk of his patent being revoked for failure to manufacture in Great Britain. With this view we disagreed, and it is evident that the American Consul's reading is not "generally accepted," for our opinion has received endorsement in many quarters. The whole question depends on the meaning attached to the word "manufacture," for the Act is clear that the patented article must be manufactured in this country if the patentee is to resist successfully an application for the revocation of his patent. So far as we know, there has been no judicial definition of the word "manufacture." Cases heard under the Merchandise Marks Acts are always complicated by the consideration of what is the trade custom, as the point that comes up for decision is whether there has been false trade description. Turning, however, to the meaning attached to the word manufacture by Dr. Murray's dictionary, which must be accepted as a leading authority, we find: "The action or process of making articles or material (in modern use, on a large scale) by the application of physical labour or mechanical power." This in itself may not help to draw a distinction between manufacturing and assembling, but two of the examples which Dr. Murray chooses as typical of the correct and accepted use of the word clearly settle the question. The first is from Bacon: "This law pointed at a true principle; that where forraine materials are but superfluities, forraine manufactures should be prohibited. For that will either banish the superfluitie or gain the manufacture"—almost anticipating the intention of Mr. Lloyd George's clause, although written in 1622, two hundred and eighty-five years previously. Another example given of the correct use of the word is more recent, dated 1892, and is as follows: "The tin which they needed for the manufacture of bronze." From this it should be quite clear that in general terms assembling and manufacturing are not identical in meaning; and if, therefore, foreign patentees wish to protect their British patents, they will find it hard to evade the obligation of actually manufacturing in this country.

ARRANGEMENTS FOR THE WEEK

TO-DAY (THURSDAY), JANUARY 7TH.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton House, Westminster, London. Paper to be read:—"Specifications for Engineering Works," by H. Lawrence Butler.

Rontgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London. Paper to be read:—"A Description of Three Sub-standards of Radio-activity Recently Prepared for the Röntgen Society," by C. E. S. Phillips. Mr. H. C. Head will show a new localising apparatus

TUESDAY, JANUARY 12TH.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University. Paper to be read:—"The Improvement of Power Factor in Alternating-current Systems," by M. Walker.

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Meeting at 207 Bath Street. Paper to be read:—"The Wiring of Buildings," by D. S. Munro.

WEDNESDAY, JANUARY 13TH.

Institution of Electrical Engineers: Birmingham Local Section.

7.30 p.m. Meeting at the University. Paper to be read:—"Practical Considerations in the Selection of Turbo-alternators," by Dr. M. Kloss.

Association of Engineers-in-Charge.

8 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street, London. Paper to be read:—"Water and its Impurities," by J. B. C. Kershaw.

THURSDAY, JANUARY 14TH.

Junior Institution of Engineers.

7.30 p.m. Meeting at the Royal United Service Institution, when Prof. J. T. Nicolson will lecture on "The Laws of Heat Transmission in Steam Boilers as Deduced from Experiment."

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read:—"The G.B. System from a Tramway Manager's Point of View," by Stanley Clegg.

FRIDAY, JANUARY 15TH.

Northampton Institute Engineering Society.

5 p.m. Meeting at the Institute, St. John Street, Clerkenwell, London. Paper to be read:—"Proportionment of Armature Teeth," by H. K Whitehorn.

SATURDAY, JANUARY 16TH.

Junior Institution of Engineers.

3 p.m. Visit to the Engineering Laboratories and Workshops of the City and Guilds Central Technical College, Exhibition Road, South Kensington

THE RELATIVE PROPORTIONS OF COPPER AND IRON IN ALTERNATING- AND CONTINUOUS-CURRENT GENERATORS

By A. G. Ellis

IN an article in last week's ELECTRICAL ENGINEERING, the dependence of the weight and cost of large generators on the speed and output was considered; and it was shown that for alternating-current generators the total weight and cost per k.v.a. both decrease as the rated speed increases, until a certain most economical speed is reached, above which both quantities increase again. In the case of continuous-current generators the cost per kw. likewise reaches a minimum at a certain rated speed, but the weight per kw., on the other hand, appears to reach a certain value and then remain practically constant with increase in rated speed. This divergence is due to the combination of circumstances which render a high-speed continuous-current machine of a given rated output, more expensive than a low-speed machine of the same rated output, or as compared with a high-speed alternator of the same rated output. The first of these circumstances relates to the fact that there is a larger proportion of copper in the C.C. generator than in the A.C. generator. This is clearly shown by the curves in Figs. 1 and 2, in which the cost of copper and iron per kw., and the total cost of the *effective* material per kw., are plotted as a function of the rated speed. It will be seen that except at very high speeds the total cost of effective material per kw. is appreciably higher for C.C. machines than for A.C. machines. In addition to this, it will be noticed that in C.C. machines the copper cost is a much greater proportion of the total effective cost than in A.C. machines. This is shown by the curves in Figs. 3 and 4, where the costs of copper and iron respectively are plotted as percentages of the total effective cost. These curves show that for C.C. designs, over practically the whole range of speeds, the copper cost constitutes on the average some 55 per cent. of the total cost of effective material; the iron constituting the remaining 45 per cent. These figures are reversed for A.C. designs (except for the lowest rated speeds), in which the copper cost averages rather less than 35 per cent., and the iron rather more than 65 per cent. of the total effective cost.

This preponderance of copper in C.C. designs as compared with A.C. designs is due to the commutation restrictions in the former and pressure regulation limitations in the latter. Lower values for the armature strength (as expressed in armature ampere-turns per pole) are employed for A.C. machines than for C.C. machines, chiefly on account of the pressure regulation limits in the case of the former. Hence relatively larger values of the total flux crossing the air gap are required for A.C. designs. These lead to larger magnetic sections, greater amounts of magnetic material, lower output coefficients, and heavier weights. Comparing the weights of copper and iron, it is seen that the percentage which the weight of copper constitutes of the total weight of effective material averages 30 per cent. for C.C. machines, as against 15 per cent. for A.C. machines. Thus every 100 kg. of copper and iron in a C.C. machine will be composed of some 30 kg. of copper and 70 kg. of iron, as against 15 kg. of copper and 85 kg. of iron in an A.C. machine.

The cost of these materials in shillings, taking copper

FIGS. 1–4.—CURVES SHOWING THE RELATIVE COSTS OF COPPER AND IRON FOR C.C. AND A.C. GENERATORS.

Digitized by Google

at 1s. 6d. per kg. and iron at 6d. per kg., are as follows:—

	C.C.	A.C.
Cost of copper	45	22
,, iron	35	42
,, copper and iron	80	64
,, per kg. (for 100 kgs.)	0·80	0·64

Apart from these considerations of the composition of the effective material, there is the additional fact that the copper in the machine takes the form of windings of some description, or of a commutator. The labour charges for the windings are much greater than those associated with an equal weight of iron in a machine. This is largely due to the fact that a larger proportion of the material and labour charges associated with the copper in C.C. machines is involved in the commutator, compensating windings, and other sparking preventive devices.

The divergence between weight and cost at low and high speeds is brought out in an interesting way by a comparison of designs for 200 and 2,000 r.p.m. For continuous-current generators the average weights and costs of material, and the Total Weight and Total Works Cost per kw., as obtained from the preceding curves, are as follows:—

Rated speed r.p.m.	200	2000
Cost of iron— shillings per kw. ...	5·0	2·2
,, copper ,, ,, ...	7·0	2·8
,, copper & iron ,, ,, ...	12·0	5·0
Total Works Cost ,, ,, ...	28	19
,, Weight per kw.—kg.	33	13
,, Cost per kg.—shillings	0·85	1·45

By increasing the rated speed ten times, viz., from 200 to 2,000 r.p.m., the total weight is decreased by some 60 per cent., but the total works cost is only decreased by some 32 per cent.

Let us now compare these figures with similar figures for polyphase A.C. generators at the same rated speeds, viz., 200 and 2,000 r.p.m. The weights and costs obtained from the curves are as follows:—

Rated speed r.p.m.	200	2000
Cost of iron— shillings per kw. ...	4·3	3·5
,, copper ,, ,, ...	4·0	1·5
,, copper & iron ,, ,, ...	8·3	5·0
Total Works Cost ,, ,, ...	28	14
,, Weight per kw.—kg...	33	20
,, Cost per kg.— shillings	0·85	0·68

In this case, increasing the speed ten times as before occasions a 40 per cent. decrease in the Total Weight, and a 50 per cent. decrease in the Total Works Cost. These figures are brought together in the following table:—

Percentage decrease in Total Weight and Total Works Cost for an increase in rated speed from 200 to 2,000 r.p.m.

	AC.	CC.
Per cent. decrease in Total Weight ...	40	60
Per cent. decrease in Total Works Cost...	50	32

Thus, as the rated speed is increased, the total works cost of C.C. machines decreases at a considerably less rate, as compared with the decrease in total weight, than in the case of A.C. machines. At low speeds the Total Weight and Total Works Cost have respectively about the same values per kw. for both C.C. and A.C. machines. Hence, as will be seen from the above table, a C.C. generator weighs less but costs more than an A.C. generator of the same rated output. Continuous-current machines for high speeds are not at present practicable propositions for outputs greater than 1,500 kw. Hence in further comparisons between C.C. and A.C. generators it will be a more fair procedure to consider A.C. generators up to this limit of rating. For this purpose we have taken mean curves through the 375, 750, and 1,500 k.v.a. curves in Figs. 5 and 6 of the article on this subject in the issue of December 31st last. These mean curves represent the average weight and cost per k.v.a. for alternators up to 1,500 k.v.a. We have also taken similar mean curves through the curves which were given for continuous-current machines. These mean curves represent the weight and cost per kw. for continuous-current machines up to 1,500 kw. In order to avoid confusion, these mean curves were not drawn in these figures, but they are drawn respectively in Figs. 5 and 6 above. The curves show comparisons between the weight per kw., and also between the cost per kw. for C.C. and A.C. machines. These curves bring out very clearly the points which have been observed and explained above, viz., that at high speeds C.C. machines weigh less, but cost more per kw. than A.C. machines. It will be noted that for the customary range of rated speeds of steam turbines C.C. machines cost from 30 per cent. to 50 per cent. more than A.C. machines.

From the curves in Figs. 5 and 6 we are able to obtain values for the total cost per kg. of total weight

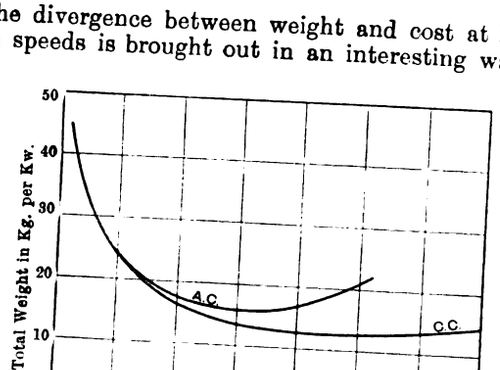

FIG. 5.—WEIGHT PER KW.

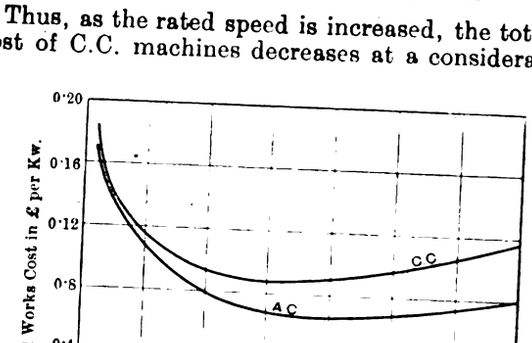

FIG. 6.—COST PER KW.

FIGS. 5 AND 6.—AVERAGE CURVES FOR WEIGHT PER KW. AND COST PER KW. FOR C.C. AND A.C. GENERATORS UP TO 1,500 KW. RATED OUTPUT.

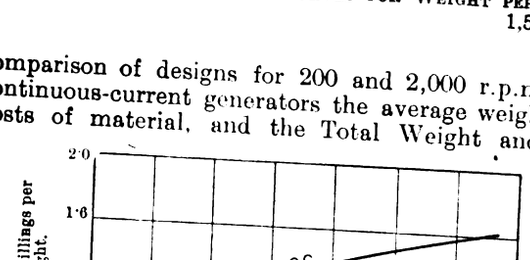

FIG. 7.—COMPARATIVE COST PER KG. OF TOTAL WEIGHT FOR ALTERNATING-CURRENT AND CONTINUOUS-CURRENT GENERATORS.

Digitized by Google

by dividing the cost per kw. by the weight per kw. These values are plotted in the curves of Fig. 7. For low and medium speeds there is very little difference in the cost per kg. for C.C. and A.C. machines. At 1,200 r.p.m. a C.C. machine costs some 50 per cent. more per kg., or half as much again, than an A.C. machine; while at very high speeds the cost per kg. of a C.C. machine is practically double that of an A.C. machine. These differences are due to the preponderance of copper in C.C. machines, and to the extra labour costs associated with high-speed C.C. machines, which render them more costly pieces of apparatus than A.C. generators when compared weight for weight. By way of further comparison, we have drawn Total Weight and Total Works Cost curves for C.C. and A.C. machines for a number of definite ratings. These curves bring out more clearly certain points which were not revealed in the previous curves, owing to the A.C. and C.C. curves being for machines of different rated outputs. Such curves have been drawn in Figs. 8 and 9 for rated outputs of 375, 750, and 1,500 kw. for both C.C. and A.C. machines, and also for 3,000 kw. A.C. While the conclusions which may be drawn from this set of curves are substantially the same as those brought out by the previous curves, nevertheless several matters appear in a different light by presentation of the data in this manner, as an inspection of the figures will show.

Thus a machine of 375 kw. rated output has practically the same weight and cost whether for continuous current or for polyphase alternating current; and this is the case over quite a considerable range of speeds. Beyond this range of speeds the curves diverge. The same observation applies to the 750 kw. rating, with the exception that the range of speeds over which the curves practically coincide is smaller than in the case of the 375 kw. rating. For the 1,500 kw. rating the A.C. curve is considerably below the C.C. curve over the whole range of speeds. By adding to this series the curve for a 3,000 kw. A.C. machine, it may be seen that a 3,000 kw. alternator costs only some 20 per cent. to 35 per cent. more than a 1,500 kw. C.C. machine, according to the rated speed. This again emphasises the conclusion arrived at above, viz., that in medium and large ratings and at moderately high speeds the A.C. polyphase generator costs considerably less than the C.C. machine. In addition to this the A.C. high-speed generator is far more satisfactory as regards design and operation than the high-speed C.C. generator.

ELECTRICAL POWER COMPANIES

(By a Pessimistic Correspondent)

SOME seven or eight years ago a Parliamentary Committee, presided over by Viscount Cross, and known since to the engineering world as "Lord Cross's Committee," recommended far-reaching changes in the electrical procedure of the country. Up to that time private companies and municipalities had been given the right to make and sell electrical energy in areas strictly limited by geographical positions; they were allowed to deal in electricity in areas—*qua* areas—without reference to the fact that their power-houses might equally well serve adjacent districts, and by centralisation of running, management, and capital charges, produce an article that could be sold at wholesale, instead of retail, prices. The recommendations of Lord Cross's Committee partly changed this. Their carefully considered verdict found that the supply of electrical energy for power purposes should be permitted over much larger areas than formerly, subject to safeguards of vested interests. Within a year or so of the Committee's findings, the whole of industrial Great Britain was divided out amongst some twenty or more electrical power companies, each having statutory power to supply electricity over areas of hundreds of square miles.

Municipalities, meanwhile, were supplying a good and cheap light, and were rapidly developing their tramway systems, which, to-day, are amongst the greatest blessings of municipal enterprise. The enquirer after electricity for power purposes was—except in a few towns—quoted prohibitive rates. The rest of the civilised world had realised the economy, adaptability, and safety of electricity as a means of obtaining mechanical power, and scheme after scheme was initiated and carried to a successful issue.

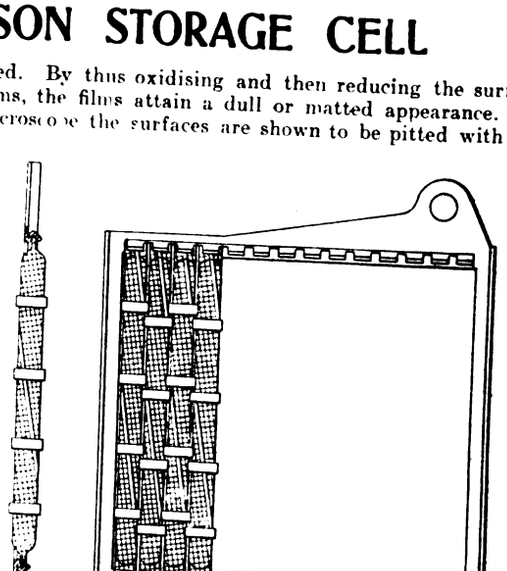
The Acts of Parliament obtained by the various power companies, while giving them the right to supply large districts, excluded them in nearly every case from areas that already possessed an electricity undertaking. The call for power, outside the large towns and cities, and the ofttimes wide areas possessed by district councils, is so scattered that the power companies cannot sell at a profit to themselves and to their consumers. The capital cost of, and the inevitable losses in, distribution and transformation, make it impossible, in nine cases out of ten, for the power company that needs output to sell to the isolated manufacturer who requires cheap power.

In the early days of power companies great stress was laid on the fact that they would be able to generate energy at a low cost. They could go where land was cheap, water and coal handy, and rates moderate. This is true, but the cost of producing electricity is but a small part of the total cost of getting it to the customers' lamps or motors. The capital charges in nearly every power company at work to-day are so high that they must either lose custom or sell at a

Digitized by Google

loss. The cost of obtaining the Acts, preliminary expenses, and management and development expenses during construction, have been high, and all this is so much dead capital. The money market was tight when power companies came into being, and payment for buildings, plant, and mains has in most cases been partly made in shares, with the result that they have cost more than they would have done had they been bought in the open market. Instead of beginning in a small way and developing one part of their area, keeping in view the urgent need of an early dividend in order to give the investing public confidence, most of the companies launched out into heavy expenditure. In some cases more than one power-house was erected, and in every case mains were laid down without any immediate prospect of their paying.

It may be argued that a power company must give a supply before it can create a demand, and there is a good deal of truth in this. On the other hand, it may be fairly urged that fuller knowledge of the power requirements and the cost of supply should have been obtained before money was spent. The power requirements of a district depend on its industries, and the costs of supply on the size and shape of the district, the hours that its factories work, and their average demand.



A general engineering shop, or a colliery underground haulage, where the load factor is low, can afford to pay much more for their energy than a textile mill or a colliery for ventilating, whose load factors are high. The diversity factor helps the power company somewhat, but not nearly as much as was expected. The company must give a constant supply, and its power-house is naturally equipped with large units of plant. It follows that for part of each week—in the meal hours, at night, and during the week-end—a large plant is kept at work to supply a small demand. The expense of running during these unprofitable periods—often two-thirds of the whole time—makes of naught the good costs of production that obtain during the daytime. It is not, however, in these works costs that the non-success of power companies lies. A unit may be made in the power-house for a farthing, but by the time it gets to the customer its cost has often become twopence.

As an example, a case may be taken of an imaginary company that has spent £600,000, and has one power-house equipped with 8,000 kw. of plant, together with a fair allowance of mains and transforming stations. Five per cent. is none too much to allow for depreciation, and this will require £30,000 per annum. Establishment charges—rents, rates, salaries, general expenses, insurance, etc.,—will take not less than another £7,000, making a yearly total of £37,000, or 8,880,000 pence. If the company sells one million units per annum, each unit costs 8·88d., plus the costs of production, which will bring the total cost to about 9½d. or 10d. If five million units are sold, the capital charges will be 1·776d. plus works costs, say 0·4d., a total of 2·176d. If ten million are sold the figures will be:—0·888d., plus, say, 0·3 for works costs, a total of 1·188d., and so on. With 8,000 kw. installed in the power-house, there will probably be four sets of 2,000 kw. each, one of which must be kept as a spare. This will leave 6,000 kw. available to sell from. The plant load factor will certainly not exceed 40 per cent. The plant can therefore produce 21,024,000 units per annum. At least 20 per cent. of these will be lost in distribution and transformation, leaving 16,820,000 for sale. Before the sale reaches this total it is probable that further capital will have been required for distribution, but if the original expenditure of £600,000 is sufficient, the capital cost of each unit will be 0·527d., the works costs will not be less than 0·25d., and the total cost 0·777d. per unit. If five per cent. interest is to be earned on the capital, the cost of each unit, i.e., *the price at which it must be sold*, will be 1·204d., but there is not a power company in existence that can get and keep an average price of even three farthings per unit.

IMPROVEMENTS IN THE EDISON STORAGE CELL

A PATENT recently granted to Mr. Thomas A. Edison in America outlines methods for overcoming two difficulties encountered in the manufacture of thin films of nickel or cobalt used as an addition to the active material in the inventor's alkaline storage battery. According to the *Electrical World*, New York, such films are made by electroplating a series of thin deposits on a suitable cathode, the films being separated by alternate deposits of a soluble metal which is dissolved later so as to free the nickel or cobalt films. The two difficulties encountered are as follows:—In the first place, when the films are produced by electroplating they present smooth and relatively polished surfaces, to which the particles of active material, such as nickel hydroxide, adhere with very little tenacity, even when the particles are compressed into contact with the films under enormous pressure. Consequently, when any internal movement of the active particles within the electrode mass takes place, such as may be due to the charging or discharging, the active particles separate from the films so as to spoil the contact conditions within the mass. In the second place, nickel or cobalt cannot be obtained free of all impurities under commercial conditions. The impurities principally encountered are iron and arsenic, the presence of which tend to result in the formation of oxides, which injuriously affect the contact conditions within the mass.

Mr. Edison proposes to subject the films to an operation by which an oxidation will take place, penetrating a very slight distance below the surface. This oxidation is effected by heating the films in an oxidising atmosphere. The effect is not only to oxidise the surface particles of the metallic films, but also to oxidise the metallic impurities, such as iron or arsenic. After this the films are subjected to the reducing effect of hydrogen in the presence of heat, and the oxides are reduced to the metallic state. The films are then subjected to an acid treatment, which has the effect of dissolving out any metallic impurity. It is said that the treatment described does not objectionably affect the surface of the films, as the nickel or cobalt is only slightly attacked. By thus oxidising and then reducing the surfaces of the films, the films attain a dull or matted appearance. Under the microscope the surfaces are shown to be pitted with minute irregularities, the effect of which, when the active material is tightly compressed into contact with the films, is to increase enormously the adhesion between them.

IMPROVED STEEL GRID FOR HOLDING THE POCKETS OF THE EDISON STORAGE CELL.

Digitized by Google

The accompanying illustration shows an improved form of plate, also patented by Mr. Edison. Numerous pockets containing active material are secured to a conducting frame, the arrangement being such as to permit the ready removal of any pocket without disturbing the other pockets. The grid shown consists of a thin plate of nickel-plated steel, stamped to provide one or more openings of rectangular form, the upper and lower edges of which are formed with flanges having integral tongues corresponding in number to the number of pockets which are to be applied to the opening. The pockets shown are in the form of tubes of perforated metal filled with active material, the ends of the tubes being compressed or flattened, and the flanges in which the tongues are formed are bent away from the opening, as shown. When the tongues are at right angles to the flanges, the pockets may be placed in position, and the tongues are then bent toward the flanges into the position shown, thereby firmly securing the flattened ends of the tubular pockets and holding the same in conductive relation to the grid. Any one of the pockets may be removed from the grid by bending the upper and lower securing tongues which hold it, and a new pocket substituted, the tongues being then bent back into holding position without disturbing any of the other pockets carried by the grid.

REVIEWS OF BOOKS

Outlines of Electrical Engineering. By Harold H. Simmons. 914 pp. 9½in. by 6½in. 923 illustrations. (London: Cassell & Co.) 21s.

IT is a little difficult to know exactly to what class of reader the brave author who attempts to outline the whole subject of electrical engineering in one volume appeals, but, from the appearance of works such as this from time to time, we must take it for granted that a demand for this somewhat unsatisfactory class of technical literature exists. The difficulties in such a compilation are necessarily great, and the lack of uniformity shown in the present work may be to some extent unavoidable. Thus, in some parts, as, for instance, in the section on electrotyping, elaborate and sometimes almost extraneous detail is included, while the treatment of other sections of the subject is too superficial to be of much use. The earlier part of the book is not always quite true to its title, as the general summary of electrical phenomena sometimes wanders into semi-historical matters which hardly come under the heading of electrical engineering. Again, the object of the early semi-theoretical part is a little difficult to understand. The sequence is not sufficiently logical for it to form a good course of instruction in the principles upon which electrical engineering is based, nor is the arrangement satisfactory from the point of view of a work of reference to refresh the memory. In short, as an educational work it is too haphazard, as a cyclopædia it is too diffuse.

Taking the more practical sections of the book in greater detail, much of the section on instruments is good, particularly that relating to galvanometers, which gives an excellent idea of forms in general use; but among the illustrations a very antiquated form of ammeter has crept in and is described as a modern form of instrument. Apparatus of as recent introduction as the latest form of Dr. Sumpner's wattmeter is, however, described. The succeeding section on testing is, on the whole, a good *résumé* of methods, but is not always quite reliable as to their practical applications. The self-contained potentiometer, for example, excellent as it is for a number of purposes where accuracy is desirable, is not the most suitable apparatus for connecting direct to machines for a Hopkinson test. The section on alternating currents is very clear, and might well be studied by a student anxious to obtain a grasp of the principles involved. The author is evidently at home in this part of his subject, and we specially commend the vector diagrams relating to transformers.

After this, we plunge again into the very elementary. The chapters on the dynamo contain the inevitable caricature of the "ideal simple dynamo," with a diminutive crank handle but innocent of bearings. Happily, however, we are spared the usual page of diagrams of "various forms of field magnets." The quality of the chapters on machines, however, makes up for a great deal, and the illustrations are more up-to-date than in the earlier part of the book. The arrangement both here and a little later on is capable of improvement, as the single phase commutator motor is out of place under induction motors, and the Tirrill regulator is described under the heading of works testing.

The section on metal filament lamps is scanty and inaccurate. It is a great pity that the serious error should have been made of describing the wire-drawn tantalum "filament" as being made by the squirting process. Again, we believe we are correct in saying that osmium does not enter in the construction of the "Osram" lamp. The arc lamp chapter would have been made more up-to-date by a description of an enclosed flame arc lamp as well as the ordinary forms. A great deal of information of a real engineering nature is compressed into the following sections on interior wiring, switchgear, and balancers and boosters, but here, again, the arrangement will bear improvement. The section on cables is largely a catalogue of joint boxes and feeder pillars. In the three chapters on tramway practice, there are a number of excellent illustrations collected from various sources. Besides brief notes on the overhead system, there are short descriptions of the L.C.C. conduit and the Lorain, Dolter, and G. B. surface contact systems. Only a few pages can be spared for the important subject of electric railways, and, after a recapitulation of some of the principles of ordinary telegraphy, chapters are given on electric oscillations and waves, which pave the way to a useful digest of wireless telegraphy, for which Mr. R. P. Howgrave Graham is responsible, and the value of which is much enhanced by frequent references to literature where more extended information is to be found. The succeeding chapter on telephony might well serve as an introduction to the intricacies of exchange working. The last chapter deals with the erection of poles.

In conclusion, we would suggest that had the author confined himself strictly to outlining the engineering applications of electricity without attempting to teach the principles of electricity and magnetism in the same book, a more homogeneous and useful volume might have resulted.

The Practical Electricians' Pocket-Book for 1909. Edited by H. T. Crewe. 352 pp. 5¼ ins. by 3¾ ins. (London: S. Rentell and Co.) 1s.

To compile an electrical pocket-book for the use of the wireman, jointer, dynamo, and arc lamp attendant, is a task requiring more skill on the part of an author than to arrange compressed information for ready reference by those whose training gives them a better grasp of the subject, as there is always the danger of instilling only that little knowledge which is a "dangerous thing." In the present little book a brave attempt has been made, but in the endeavour to cover as wide a range as possible, much of the information is too superficial to be of much real use in practical work. There is, however, a very fair amount of tabular and real pocket-book matter, and a list giving the voltages, &c., of the principal metropolitan and provincial supply authorities. Another feature is the provision of blank forms to assist in getting out estimates for wiring work. Considerable attention has been given to revision, and a certain amount of new matter has been added, but in the sections on lighting the work can hardly be said to be up to date, as no information as to the use of 25-volt metal filament lamps is included.

Imports of Electrical Goods into Turkey.—From a list of goods sent by H.M. Ambassador at Constantinople, the importation of which, under the old *régime*, was either entirely prohibited or subjected to special restrictions, but which are now freely admitted, it is seen that all sorts of electrical appliances, including telephones, come under the new regulation.

THE LONDON COUNTY COUNCIL TRAMWAYS AND THE SNOWSTORM

TRAFFIC on the London County Council tramways was much disturbed last week owing to the sudden heavy fall of snow. As happened on a similar occasion two years ago, considerable trouble was occasioned by the salt which was thrown on the roads by the road authorities to melt the snow. The wet saline mixture caused leakage across the contacts of the ploughs, and there was a certain amount of sparking and in some cases slight fires. The majority of the ploughs are provided with moulded rubber bases and are impervious to moisture, but the surface leakage must have been great, owing to the peculiar conditions. It must be added, however, that the effect on the ploughs was a minor cause of the dislocation of traffic and was much less in evidence than after the snowstorm two years ago. The chief disturbance and delay was due to horse-driven vehicles getting on the track and being unable to move off it, fallen horses, and similar accidents that blocked the tramway lines.

SPRING-SUPPORTED GEARED TRACTION MOTORS

AN interesting feature of the geared single-phase traction motors which the Westinghouse Co. are building for the new motor-car trains for the New York, New Haven, and Hartford Railway, is described in the *Electric Railway Journal* (New York). This consists in the suspension of the motors entirely on springs, an arrangement which should do much to reduce the wear on the track and road-bed, and should give to the cars exceptionally easy riding qualities. The arrangement of

DETAILS OF SUSPENSION OF GEARED SINGLE-PHASE MOTOR FOR NEW YORK, NEWHAVEN, AND HARTFORD RAILWAY.

the spring supports, as well as the principal dimensions of the motor, are shown in the accompanying figure.

The essential element of the arrangement is a "quill" similar to those on which the armatures of the gearless motors for the locomotives are mounted. This was described and illustrated in ELECTRICAL ENGINEERING, Vol. II., page 408. In the present instance, however, the quill encloses the axle, instead of forming the armature shaft, and is carried from each wheel by means of four pins located in spring pockets in the wheel, and surrounded by eccentrically wound helical springs. The motor and gear are mounted upon this quill. By this arrangement the gear centres are rigidly maintained, while at the same time a spring support is secured for that part of the motor weight which is usually carried directly on the axle. The remainder of the motor weight, which is ordinarily carried by means of the motor nose, and supported solidly from the transom of the truck, in this case is carried on a spring cradle as shown. Thus the entire motor is spring-borne.

Each motor, which has six poles, has a nominal rating of 150 h.p. on the one-hour rating, with forced ventilation, and may be operated continuously at approximately 75 per cent. of its one-hour current rating. The field winding is of the compensated-series type, and the armature is provided with preventive leads. Use is made of partially closed slots in the armature core and an especially rigid commutator construction. The leads have been brought out on the axle side instead of the bolster side of the frame, so that they may be secured without interference from truck parts or brake rigging. The weight of the motor, complete with gears, gear case, axle bearings, and quill, is approximately 7,450 lb., and of the motor only, approximately 5,600 lb. The quill complete weighs about 1,400 lb.

THE PREVENTION OF BOILER ACCIDENTS

THE annual report for the year 1907 of Mr. C. E. Stromeyer, Chief Engineer to the Manchester Steam Users' Association, has recently been published, and contains a good deal of interesting information relating to boiler construction. The report embodies the results of a series of experiments on samples of British- and foreign-made boiler-plates of various chemical constitution, including parts of boilers which had failed in practice. The investigation was particularly directed to ageing effects.

Generally speaking, the result of the inquiry, as far as it has extended, is that none of the numerous mechanical tests which have been tried can be said to have given more trustworthy information about the reliability of steel plates than is obtained by the usual workshop manipulations, including the hydraulic test, and it may also safely be said that although both practical experience and some of the tests which were carried out unmistakably indicate that mild steel possesses ageing properties, yet no explosion or other mishap can be attributed to age alone. Those very few accidents, for which definite causes have not been discovered, may, for the present at least, be attributed to improper manipulations in the workshops, more particularly as in one or two of these cases there is a suspicion that some of the failed plates may have been bent while blue hot, which is a temperature at which mild steel and wrought iron become permanently brittle if bent.

The succeeding section of the report is devoted to the question of explosions caused by water-hammer, and formulæ are deduced for the pressures developed. Regarding the prevention of this danger, the opinion is expressed that snifting valves to admit air into the pipes when steam is cut off are of but little use, but that the only efficient safeguard against explosion is to fit automatic draining arrangements which will prevent water from accumulating in the pipe either when steam is turned on or off.

In conclusion, the report comments on the existing system of boiler inspection as provided for under the Factory and Workshop Acts, and calls attention to the lack of a proper definition of a "competent person" and the absence of penalties in the case of employment of an obviously incompetent boiler inspector.

International Exhibition at Nancy.—H.M. Consul-General at Paris has forwarded a copy of the programme of an international exhibition, under the patronage of the French Government, to be held at Nancy from May to October, 1909. The exhibition will comprise sections devoted to mining, metallurgy, transport, electricity, textile and chemical industries, &c. Applications for space will be received by the Director-General of the Exhibition up to February 1st next. A copy of the programme and a plan of the exhibition may be seen by British firms interested, on application at the Commercial Intelligence Branch of the Board of Trade.

The "Electron."—The December issue of the Siemens Stafford magazine of this name includes a special supplement consisting of portraits of the well-known original Siemens Brothers, Werner, William, and Carl. The frontispiece of the actual issue depicts a living representative of the von Siemens family in the person of Mr. Carl Friederich von Siemens, younger son of the great Werner von Siemens, lately managing director of Messrs. Siemens Brothers' Dynamo Works, Ltd., but now director of all the overseas business of the various Siemens concerns. The presidential address of Mr. F. W. Schiller to the Siemens' Stafford Engineering Society occupies the greater part of the issue, but is followed by several shorter original contributions and the usual chronicles of the several Siemens' societies and clubs.

THE REGULATION OF ARC LAMPS WITH CONVERGING CARBONS

THE results of some experimental researches into the conditions which determine the steady burning of flame arc lamps, in which the arc is maintained between chemically impregnated carbons, have been published in a recent issue of the *Elektrotechnische Zeitschrift* by Dr. J. Teichmüller, of Karlsruhe. The experiments, which were carried out on a Siemens-Schuckert continuous-current differentially wound lamp with an escapement feeding mechanism, relate to lamps with downwardly converging carbons. This arrangement of converging carbons, which gives a better distribution of light than the axial arrangement, is only rendered possible by the use of a magnetic field to spread out the arc and keep it at the carbon-tips. This is especially the case with the smaller sizes, as then the magnetic field produced by the arc circuit itself is insufficient to prevent the arc from running up the carbons under the influence of the air-currents. When the current taken by the arc is comparatively heavy, the magnetic field produced by the arc circuit itself is enough to throw the arc downwards and spread it out to a certain degree, but even then it is advisable to have an additional controlling field to steady the arc. The article in question deals particularly with the function of this additional field, and its effect on the regulation of the arc and feed of the carbons.

Dr. Teichmüller commences by pointing out that the arc between converging carbons is much more sensitive than that between axially arranged carbons, and that in the case of flame arc lamps, the sensitiveness is even greater owing to the use of cored carbons. Not only is an unpleasant flickering produced by the unavoidable inequalities in the consistency and amount of the impregnating chemicals that are fed into the arc as the carbons burn away, but these inequalities have a very bad effect on the working of the feeding and regulating mechanism. For example, should there be a sudden decrease in the amount of chemicals supplied, or should the arc be blown from the core to the outer carbon covering, the resistance of the arc will suddenly increase, and the feeding mechanism will come into operation, as if the arc had actually lengthened; this brings the carbons much too near together, and causes a sudden increase in the current. The series coil and regulating mechanism will, of course, tend to draw the carbons apart again, but as the lamp has "over-fed," this will only bring about a partial return to the normal conditions. Much of the flickering mentioned above is due to this erratic working of the feeding mechanism. Under the above conditions, the feeding of the carbons will take place irregularly, and at relatively long intervals, whereas for a steady arc, the feeding should occur regularly, and at short intervals, determined by the natural burning down of the carbons. The length of carbon dropped at each feed should also be relatively small. To obtain this regular feed, it is necessary that the cores should be homogeneous, and that the arc should be kept to the core tips.

With regard to the function of the controlling magnet, Dr. Teichmüller asserts that although it is often thought to assist and even be the chief cause of feeding, it has really quite a different effect, as with carbons converging at a fairly wide angle, the natural burning of the carbons and the consequent lengthening of the arc is enough to operate the feeding mechanism. It was thought that it was necessary to lengthen the arc artificially as the carbons burnt away by causing it to approach a magnet placed above, but Dr. Teichmüller expresses the opinion not only that there is no need for this, but that a magnetic field across the arc in general has exactly the opposite effect—namely, tends to prevent the arc from lengthening, by keeping the arc at the tips where it can receive "nourishment" from the impregnated cores and maintain a steady resistance. If the arc is not kept to the tips of the carbons, any irregularity in the consistency of the cores or any draughts may cause "over-feeding," and an unpleasant flickering of the light as previously mentioned.

The lamp experimented on was a 12-ampere lamp, and it was run off a battery in order that a constant terminal voltage should be ensured. Arrangements were made for recording automatically the entire movements of the carbons, together with the time intervals between the feeds. The positive carbon only was cored and the average pressure across the arc was 84 volts. Different arrangements of the controlling field magnet were tried, and the angle between the carbons was varied; the position of the arc relatively to the economiser was kept as constant as possible. The controlling magnet was separately excited. The results of the experiments showed that although the controlling magnetic field did not directly lengthen the arc and thus assist the feeding, it did increase the number of "feeds" for a given length of carbon consumed, by causing the carbons to be fed regularly and in small amounts, and by preventing the irregular and large feeds consequent upon an unsteady arc. For example, with the carbons set at an angle of 23°, the number of feeds for a given length of carbon consumed with a magnetic field were nearly double what they were without any field. A homogeneous field across the arc had a greater steadying influence, and caused a larger number of feeds to take place for a given length of carbon consumed than a field increasing from below upwards. The latter result conclusively proved that the approach of the arc into a stronger field as the carbons burnt away was not the cause of frequent and regular feeding, but that it was the maintaining of the arc at the tips of the carbons where it could keep a steady resistance which was the object to be aimed at. The number of feeds for a given length of carbon consumed were nearly one-and-a-half times as many with the homogeneous field as with the field increasing upwards, with angles between the carbons of 15° to 20°, but with an angle of 6° the number of feeds was somewhat less in the former case. A more regular feed, however, was obtained with the homogeneous field with any angle. Dr. Teichmüller is unable to explain fully why the effect is reversed with a small angle, but this fact is relatively unimportant, as such an angle would hardly be employed in practice.

In conclusion the method and apparatus used in the experiments are proposed as a means of testing carbons and arc lamps. With a given mechanism, the regularity and the number of feeds for a given length of carbon is a test as to the quality of the carbon; the better the carbon, the more regular and steady is the arc, and the larger the number of feeds. Again, if a known quality of carbon is used, and the apparatus is fixed to different lamps, the results obtained will give relative values as to the efficient working of the respective lamp mechanisms.

THE INFLUENCE OF CHEAP ELECTRICITY ON ELECTROLYTIC AND ELECTROTHERMAL INDUSTRIES

A PAPER with the above title was read by Mr. E. A. Ashcroft, before the Faraday Society on December 21st. The author pointed out that the large developments at Niagara Falls had familiarised the world with the possibilities of water-power; but had also brought certain limitations to light; for even at Niagara the price of energy to the consumer never could be low enough to satisfy the rigid economical demands of many, technically possible, industrial processes which would soon become commercially possible with sufficiently cheap energy. If Niagara power were too dear, steam, gas, and oil engine, for the purposes above stated, could have no chance at all. For even if free supplies of fuel were available, the capital charges and the upkeep would still bring the cost of the unit of electricity somewhere about the level of the Niagara prices, and still far above the "low-grade limit" which will be demanded by the coming new industries. The author put this "low-grade limit" at about £2 per kilowatt-year, and remarked that no means of producing energy at present known could touch this limit except water-power under favourable conditions.

Table I.

Cost of electricity produced from water power :—

Item.	Class II. Per Kw. Year. £ s. d.	Class I. Per Kw. Year. £ s. d.
Fuel	—	—
Labour	0 8 0	0 6 0
Upkeep	0 13 0	0 8 0
Capital charges	4 2 0	0 13 0
Royalties on rights ...	0 3 0	0 13 0
Total	5 6 0	2 0 0

In Table I. taken from the Paper, estimated costs of water-power are given, Class I. referring to conditions favourable to

Digitized by Google

development without much expenditure of capital, and Class II. to an average of less favourable cases.

The best practical source of energy "in bulk" to-day, continued the author, is the favourably-placed waterfall, and the second best is a waterfall of Class II., which may also sometimes have the advantage of being obtainable nearer home. A growing demand for large gas and oil motors, however, is indicated by the state of the markets to-day, a circumstance which is explained by the fact that many operations consuming energy are absolutely bound to be carried out at spots where no waterfall can be obtained. Moreover, in the particular industries considered here quite a large demand may yet arise for gas and oil engines; for there are indications of a tendency to devise apparatus wherein a combined use is made of electro-thermal (or electrolytic) and of direct combustion principles. Thus it has been suggested that a charge of iron ore, carbide materials, or similar raw materials, might be heated up by ordinary fuel combustion to nearly the required temperature and made thus to imbibe a large number of necessary heat units at a cheap rate, and then finished off by raising it to final temperature, with the aid of the more expensive electric heat. Such operations could, of course, be carried on economically at sites even nearer to the markets than cheap water-power sites, and an advantage of some importance might be thus obtained in respect of freights.

Although electrically produced heat can probably never compete in cost, unit for unit, with heat produced from coal burned direct, yet the ratio of cost between the two is much lower than is usually supposed, whilst the ratio of efficiency brings the two still more nearly on a level, turning the balance in many cases in favour of greater economy for electric heating. One pound of an ordinary quality of coal will generate, if burned in a producer and supplied to a modern gas engine, about one electrical horse-power hour, and it will cost at the pit's mouth (at 8s. per ton) ·05d. This amount of electric energy (one electrical horse-power hour) is equal to 644,544 gram calories of heat energy. Burned directly to generate heat, one pound of coal will produce approximately 3,000,000 gram calories. Therefore by burning coal, for £1 we may procure a theoretical combustion heat of approximately 15,000,000.000 calories. The same £1 employed in purchasing electric energy at the cheapest rate (Class I., water) yields one electrical horse-power for 5,840 hours, and is therefore equivalent to 3,764,136.960 calories. This is just about one-quarter of the yield from direct combustion of an equivalent value of coal. It may be assumed that the labour and wear and tear of the furnace will, taken together, be about equal in each case. The heat produced electrically can, however, be much more usefully employed, so that a true comparison of the cost of heating processes by the two methods can only be made in the full light of experimental data determining the efficiency of each furnace or apparatus. When it is remembered that the efficiency of many non-electric furnaces is barely 10 per cent. of the theoretical and very few will exceed 25 per cent., whilst the efficiency of electric appliances sometimes reaches 75 per cent. and is often 50 per cent., it will be seen how closely this cheap power of to-day is competing with fuel combustion, even as a mere source of heat for metallurgical or chemical reductions.

The gross cost of water-power to the consumer is practically dependent on the amount of capital charges (and valuable private rights) involved. These items will vary enormously according to whether the flow of water is naturally even all the year round, or whether expensive dams must be constructed to regulate it, whether the pipe is long or short, the fall high or low, whether much valuable property is submerged by damming, and other conditions.

In general it may be stated that a capital expenditure of £7 per e.h.p. capacity is sufficient for the development of powers of Class I., including all necessaries up to the dynamo terminals; whilst some few powers which exist in Western Norway can be developed still more cheaply. On the other hand, water-powers have been developed in England and in other countries which have cost upwards of £60 per electrical horse-power for harnessing equipment and compensations. The total equipment at Niagara Falls cannot have cost less than £30 per horse-power in spite of the very large scale of operations.

The powers of Class I. (especially the best ones) are not very numerous, and their enormous natural advantages will to some extent be neutralised by the high prices which will naturally be placed on the water-rights by owners, when their true values become known and when a ready market is opened for them. Nevertheless, it is almost exclusively to powers of this type that we must look for the future of such gigantic possible developments as are suggested to-day by the looming processes of electrolytic iron, nitrate production, and the complete treatment of complex sulphide ores.

As this class of water-power seems destined to play so important a *rôle* in the near future, it will be of special interest here to give a concrete instance of such a water property and the method employed in Norway for arriving at the capitalised value of the water-right. The example is drawn from one of the most favourably situated of the many favourably placed of the small powers in Western Norway, where the existence of these sources of energy on the verge of deep water and ice-free harbours suitable for any kind of shipping, is probably unique, offering advantages to industry found nowhere else in the world in such happy combinations.

The property was acquired about eight years ago from the former Norwegian owner. The purchaser left some mortgages standing, so that the capital stood as noted below when he succeeded in obtaining title (a royal concession under the Foreigners' Exclusion Acts) to own the property. Extensive surveys had been made, the statistics of rainfall, &c., obtained, and the engineers had pronounced the waterfall (which had a fall of 1,000 feet, with a very short distance for tunnel and for pipe line from the outlet of the last lake to the lowest level) to be good for about 7,500 kw., and capable of development for less than £5 per h.p., which sum was to include also some payments to farmers for fullest damming rights. It also included the cost of damming the principal lakes at a very favourable spot, whereby, for the comparatively small sum of £5,000, enough water could be stored in the large lakes to equalise the fall completely all the year round, and so use nearly every drop of water that falls on the watershed. Though the total area of the watershed was small, viz., about 40 square kilometres, the annual rainfall is the highest in Norway, reaching 3,600 mm. per year. There was therefore enough water to secure 3·8 cub. m. per second all the year round after liberal deductions for evaporation and loss. The lake basin was large enough to secure complete equalisation of the supply. Also the intervals of drought are never very protracted when compared with such periods in countries like England. All these circumstances are most favourable for cheapest development.

The fall has a capacity of about 7,500 kw. It is supposed that a contract has been obtained for renting 6,000 kw. at an inclusive charge of £2 10s. per kw. delivered at switchboard (= £1 17s. 6d. per e.h.p.). According to estimates, the expenditure required will be as follows:—

Earthworks (including tunnel)	...	£7,988 (£1 6s. 6d. per kw.
Buildings	...	£2,666 (9s. per kw.)
Ironworks (pipe line, sluices, &c.)	...	£6,777 (£1 2s. 6d. per kw.)
Machinery	...	£21,109 (£3 10s. per kw.)
Special charges (including compensation, taxes, &c.)	...	£5,884 (say £1 per kw.)

	£
Total development cost as estimated	44,424
General margin for contingencies	5,555
Total	49,979

This expenditure can be provided for by the issue of £33,333 preference shares and £16,665 by bank loan on mortgage or debentures. The water-right can be paid for by the issue of £50.000 in ordinary or deferred shares.

The complete scheme of capitalisation will then be as follows:—

	£
Existing mortgages	13,888
Bank loans	16,665
Preference shares, 8 per cent.	33,330
Ordinary shares to owners of water rights ...	50,000
Total	113,883

The apportionment of revenue will be as follows:—

Working Expenses—

	£
Wages, materials, taxes, and administration ...	1,665
Depreciation and renewals	1,811
Total	3.476

Capital Charges—

	£
Mortgages	1.457
Bank loan (interest and redemption)	1,833

Share Capital—

	£
Preference shares at 8 per cent.	2,666
Ordinary shares at 8 per cent.	4,000
Total	13,432

Revenue—

6.000 kw. sold at £2 10s. per kw.	15,000
Margin +	1,568

Digitized by Google

This fall costs only £7 8s. per kw. to develop and equip. It is therefore possible to place a considerable value on the water-rights.

If the same revenue is obtained from another waterfall (B) which, owing to less favourable natural conditions, will cost £8 5s. per kw. to develop and equip (an average cost in Western Norway), or from a third fall (C) costing £11 2s. per kw., it can be shown that approximately the same final margin will result, omitting the ordinary shares altogether in the case of (C), and valuing the water-right at £25,000 in ordinary shares in the case of (B).

The £50,000 ordinary shares in the case of Fall (A), and the £25,000 ordinary shares in the case of (B), and nothing (by comparison) in the case of (C), therefore represents the fair valuation of the water-right, and when it is considered that the returns on these deferred shares rank after the preference shares and mortgages, and the revenue will gradually rise to 12 per cent. on all shares during the currency of the long contract by reason of the accumulation of the sinking funds for extinction of the loans, it must be allowed that the valuation is not excessive.

There have been cases in Norway where the price of electric energy is said to be still lower than the figure selected as a probable minimum, viz., £2 10s. per kw.; for instance, at Meraker, near Trondhjem, the power 3,000 h.p. has been sold at £1 5s. 6d. per h.p. on a seven years' contract, and at Notodden the price was £1 8s. for 3,000 e.h.p. It may well be that when such investments become more popular, lower returns on capital will be accepted, in which case the sale price may become proportionally lower without reducing the value of the water-right. For example, if for the development of the above-quoted waterfall, supplies of capital could be obtained at a uniform rate of 5 per cent. (including interest and sinking funds), then, leaving all other items of expense the same (including depreciation on the works and plant), the price of the energy might be reduced to £2 per kw. and the value of the water-right remain as above stated.

It is by no means certain that there exist a very large number of powers which can be developed at even so low a cost as to permit of the sale of the energy at £2 per e.h.p. year (£2 10s. per kw. year) either in Norway or anywhere else; the value of such water-rights may therefore very likely rise much above the value indicated by these estimates. For instance, if the current price of energy in the next few years finds a level at £3 per kw. year, the capitalised value of the undeveloped fall (A) in question would be about twice that shown.

It may be added that although the above valuation is self-evidently a just one, yet so little attention has been drawn to those remarkably favourable opportunities of producing cheap electrical energy with low capital expenditure and low working costs and under highly favourable conditions for its utilisation, that such values as those indicated by the above figures are not always attached to these properties as yet. How long this opportunity of reaping a large increment on capital combined with intelligence will remain open is a matter for the intelligent foreign capitalist and the Norwegian Government to decide between them.

DISCUSSION.

Mr. W. R. COOPER (communicated) pointed out that the cost of water-power was frequently what it would fetch, and that it could not be likely to have a fixed value. The price of water-power tended to rise, that from other sources tended to fall; water-power should, therefore, be purchased outright by the consumers and not merely leased. Mr. BERTRAM BLOUNT thought that the author had not done justice to sources of power other than water; the notion that very cheap power was required for all electrochemical industries was erroneous. He referred to the possibilities of electric zinc smelting among the industries requiring cheap power awaiting development. Mr. W. MURRAY MORRISON was also of opinion that steam and gas power could be produced cheaper than stated by the author—the former, in some cases, for £3 per kw.-year. The author's Class II. water-power he considered a bad specimen, and he further criticised in some detail other figures given in the Paper. He thought that not enough margin had been left for contingencies. The source of the capital was an important consideration that had not been discussed; on it frequently depended the nature and cost of labour. No two schemes were alike, and every one must be considered on its merits, taking all conditions into consideration. Mr. L. GASTER pointed out that the Niagara plant had been designed for a far greater output than had up to the present been reached, and that, therefore, the limit of cost of production of power was far below the figures at present obtaining. He suggested the desirability of manufacturing such products as graphite and carborundum at European power centres. Mr. CHARLES WEISS drew attention to the condition under which the water-powers in the Bavarian highlands were being developed. Dr. H. BORNS referred to some of the disadvantages of many water-powers, such as inconstancy of supply. Professor R. H. SMITH also remarked on the ice difficulty, which was of frequent occurrence. He did not think it possible, in the case of water-powers, to reach the low figures given by the author, and he took exception to the allowances for depreciation made in the Paper. Dr. E. FEILMANN suggested that very cheap power-gas schemes might be developed in connection with the peat-fuel industry, and he thought that large-scale experiments were being made in this direction. Mr. E. A. ASHCROFT, in reply, said his principal purpose had been to draw attention to the very special kinds of water-power that were still available, although rare, and not to contrast the various modes of power production. His figures, to which he adhered, represented a probable average. The ice difficulties referred to did not exist in Norway.

ICE-MAKING PLANTS FOR THE IMPROVEMENT OF THE LOAD-FACTOR

THE problem of flattening the load curve is always before the central station engineer, and any suggestion which appears to be capable of practical realisation is always welcome. It has often been proposed to make arrangements with electro-chemical works and other large consumers to supply power at low rates on the condition that they either cease working or work with a reduced load during the peak hours of the day, but it is generally found that it does not pay to work electro-chemical and similar processes intermittently. Another suggestion is that the station should either supply an ice-making works, or should itself manufacture ice during the non-peak hours, and the following notes, extracted from an article by Mr. A. J. Farnsworth in the *Electrical World* (New York) are of interest in this respect. The author writes:—The present methods of making artificial ice by the can and plate systems are generally well understood. Plate ice is dense and can be stored, but requires an expensive plant. Can ice will not stand storage without artificial refrigeration, and must, therefore, be made from day to day, in accordance with the demand. Both the can and plate systems freeze slowly, the average time being, perhaps, two and one-half to three days for can ice, and seven days for plate ice. They require energy steadily, and at as uniform a rate as possible, for the stoppage of the refrigerating machinery, with the resulting increase of temperature, is serious in proportion to the duration of such stoppage.

After describing the essentials of a refrigerating system for producing ice rapidly, the chief of which is that the water and the freezing surfaces should be as close as possible, as ice is a bad conductor of heat, the author describes a new process, which, it is said, has given remarkable results in this respect. Instead of the time formerly required, 11-in. ice, it is claimed, can be made in 18 hours. The ice produced is said to be dense and hard, as with the plate system, and can be stored as well as the latter, or as natural ice. The system also has several incidental advantages of importance, but to an operating company supplying such an industry with energy the chief interest in the process undoubtedly lies in the fact that energy can be furnished in varying rates throughout the day, resulting in a great improvement of the station load curve.

The process consists in forming ice upon a grid composed of parallel tinned steel or iron pipes connected at one end to a header, and with the other ends closed and rounded. The header and freezing pipes are arranged with inner tubes to secure circulation of the brine, and the grid with its ice cake rests upon the sides of the freezing tank. Connections between the grids and brine mains are made by detachable flexible tubes. Refrigerated brine is circulated through the grid, and ice forms round the pipes in cylinders, which as they grow larger unite with one another to form a cake of clear, solid ice. After the freezing is finished, the ice is allowed to remain in the water for several hours to become of uniform temperature throughout, and thus avoid internal stresses that might result in fracture. The grid with its ice cake is then lifted from the freezing tank, by means of a crane, and removed to a tilting table. Here the grid is connected to warm brine mains for a few minutes, until it becomes loosened from the ice cake, and is then pulled out of the latter and returned to the freezing tank to begin freezing another cake. The usual practice is to freeze cakes weighing from 2½ to 5 tons each. The rapid freezing is, of course, brought about by the steep temperature gradient between the freezing surfaces and the water, and also because of the small tank surface. With this system, in freezing an 11-in. cake, for instance, the heat of the water has only to be withdrawn less than 5 in. through the ice to the cold-brine pipes, or less than half as far as in the plate system.

On a test made a few months ago on a 40-ton plant in operation near New York, it is claimed that 14 tons of ice were

Digitized by Google

made on the average per ton of coal. The entire cost of ice delivered on the platform at the plant is stated to be about five shillings per ton. Depending on conditions it would be possible for an electric light company to furnish energy to a plant of this kind in several ways, as, for instance, in the form of steam direct from the boilers of the power plant, in the form of electrical energy, or possibly a combination of these two methods. The plant may start operation at any time during the evening, after the peak of the load is passed, and run continuously throughout the night and the next day until the peak comes on the following afternoon. The rate at which energy is absorbed by the ice-making apparatus need not be uniform, but may be made to conform to the available supply.

STANDARDS FOR OVERHEAD CONSTRUCTION FOR ELECTRIC RAILWAYS

A REPORT of a committee which was appointed by the American Railway Association to investigate the standardisation of conductors for electric railways, and relating to overhead as distinct from third-rail conductors, has recently been issued, and is published in the *Railway Gazette*.

A "third rail," as laid down in the definition adopted by the associated, is "an electrical conductor placed adjacent to and parallel with the track rail as a means for conducting electric current to the locomotive or cars." A conductor so placed is suitable only for an electric system employing a low potential current, say of 500 to 600 volts. Other electric systems are now in process of development using a higher potential current, in some cases up to many thousands of volts, and thus necessitating placing the conductors out of reach of the public or employees on the right of way.

Generally speaking, the requirements are: To establish an overhead conductor at sufficient height to safely clear a man standing on top of a box car under normal conditions, and at the same time to introduce approach slopes in the overhead conductor so that its height can be reduced when passing under overhead bridges and maintain a minimum safe equipment clearance. That the overhead conductor should be located in such a position relative to the running track that continuous contact with the conductor can be maintained by a sliding shoe on the car under all conditions of limitations between the maximum and minimum heights and through switches, turnouts, &c. That the height so established shall allow a certain minimum clearance between the overhead conductor and overhead construction to provide for proper insulation, and, in the case of overhead bridges, to provide for the attachment of insulators between the overhead conductor and the bridge.

In order to meet all conditions, it appears to be desirable that the overhead conductor should be located over the centre line of the track served, rather than at one side of same, although it has been suggested that to distribute wear on the sliding shoe, the conductor shall be at intervals displaced from the central position, producing a sinuous direction with a certain maximum displacement on either side of the central line.

It is necessary, furthermore, to establish certain standards in relation to the sliding shoe and its supporting mechanism, to establish the proper pressure to exert at the point of contact, the range of vertical motion to be allowed for, and the maximum length of the shoe transverse to the track, this latter to permit side clearance between the extreme positions of the shoe and signal blades and other overhead apparatus or structures. In regard to the above requirements, as before stated, it seems inadvisable to fix at present definite limitations because of the incompleteness of our information and experience as to best running conditions, but the following figures are being used experimentally in the development of the overhead conductor system:—

	500 to 2,000 volts.		2,000 to 11,000 volts.	
	Ft.	In.	Ft.	In.
Normal height of overhead conductor above top of rail	22	0	22	0
Minimum height of overhead conductor above top of rail	15	1	16	0
Minimum clearance between overhead conductor and overhead bridges		4½		10
Minimum clearance between overhead conductor and highest point of train equipment passing under same not less than...		3		12
Maximum length of contact shoe transverse to track	5	4	5	4

Maximum rate of incline in overhead conductor approaching and leaving low points, 2 ft. in 100 ft.

Proper transition curves should be provided at all vertical intersections in the overhead conductor.

The figures given above do not include installations in submarine tunnels, where special insulation and construction will modify the minimum clearances as compared with normal indications. It must be understood that the figures given are not in any way intended to be regarded as standards, even of a tentative nature. They are, as above noted, merely statements of practices now in vogue, and are given for the purpose of eliciting criticism and suggestions.

AN ELECTRICAL WINDING ENGINE INSTALLATION

A NOTE in the *Bulletin* of the Association des Ingenieurs Electriciens sortis de l'Institut Electrotechnique Montefiore of Liége describes an electric winding plant which has recently been put into operation at one of the pits of the Heinitz Mines at Beuthen, in East Silesia. The equipment, which was carried out by Messrs. Brown, Boveri & Co., is of interest, and being on a somewhat different system to some of the plants by other Continental makers

The main shaft winding plant is designed to raise 7 tons of coal per wind from a depth of 2,530ft., with a rope speed of 32·8 ft. per second, and a balance rope is employed. The electrical equipment already put down, however, is only of a capacity for dealing with 3·6 tons from a depth of 1,770 ft. with the same rope speed, but at a later date this will be added to in order to bring the plant up to its full capacity.

In this form of the Brown, Boveri system of electrical winding, a steam turbine is installed in the power station, provided with an automatic valve for by-passing live steam to the expansion stages, and this drives two machines coupled in tandem. The first of these is in a continuous-current generator, which provides the current for the winding motor, and the second machine is a three-phase alternator supplying current for auxiliary power purposes about the mine and surface works. The control of the winding motor, as in other winding systems, is accomplished by variations in the strength and direction of the generator field after the Ward Leonard principle.

The main advantage of this system is its simplicity and the small number of machines required and the ease and rapidity of starting up. No form of storage of energy other than that possessed by the boilers is made use of, and the overload capacity of the generating set is provided by the use of the high pressure by-pass valve.

The turbine, of the Brown-Boveri-Parsons design, is designed for an initial pressure of 135 lb. per sq. in., with steam at a temperature of 275° C., and exhausting into a 90 per cent. vacuum. The continuous-current generator, which supplies current to the winding motor, is provided with compensating windings on the Deri system. The mounting of the second generator for the more constant portion of the load on the same shaft is an important feature of the Brown-Boveri system, and has a very favourable effect on the steam economy and boiler conditions.

The winding engine is provided with a Koepe pulley of about 26 ft. diameter, which is at present driven by one motor, but at a later date a second motor will be added to increase the capacity of the plant as the shaft is deepened. This will entail the provision of a second turbo-generator in the power station.

WIRELESS TELEPHONY IN AMERICA

AT a recent meeting of the Boston branch of the American Institute of Electrical Engineers, Mr. A. Stein, of the National Electric Signalling Co., of Brant Rock, described some of the apparatus used in the Fessenden system of wireless telephony, and an abstract of his remarks is given in the *Electrical World* (New York). It appears that the best results have been obtained with a high-frequency alternator of the inductor type, having for its rotating part two steel slotted disks about 12 in. in diameter, running at 16,000 revs. per minute, and giving a frequency of about 80,000 cycles per second. The armature leads are connected to the antennae and earth, and by tuning with the inductance a resonance voltage is built up on the antennae to approximately 25,000 volts. Another type of high-frequency alternator under development has a single disk. For transmitting, the condenser type and the carbon type instruments have both been tried. The condenser transmitter is simply two plates that are separated by mica. The back plate is a metal sheet, and the front plate, which is directly connected to the diaphragm of the transmitter, is a gold-covered mica plate. In case the antennae are radiating energy, the condenser transmitter is shunted directly across the inductance. In talking into the transmitter the plates vary the distance, and hence the amount of leakage that goes

Digitized by Google

down the path produced by the condenser transmitter. The ordinary Bell type of transmitter was tried, but it heated so much that after three minutes' use the talking would decrease perhaps 90 per cent. In a special form two metal plates were water-cooled. Between them is a soapstone ring filled half way up with carbon. A piece of platinum is set centrally in this space between the rings, dipping into the carbon and connected to the transmitter so as to move with the talking. Other modifications have been made, and it is now easy to carry 10 amp. or 15 amp. on a transmitter without trouble. The receiver used is of the liquid type, similar to that used in wireless telegraphy. The variations in the receiver follow closely the variations in the resistance of the acid as the waves enter it. The talking is said to be clearer than on an ordinary land line. Simultaneous talking and receiving have been made possible by the use of an artificial antenna circuit. It has a capacity which is balanced against the capacity of the regular antennae, and an inductance, which is also balanced in a similar manner. The other station gets the signals because the amount of current flowing in the antenna circuit is varied by the transmitter. When the other station starts to send the antennae themselves are affected, and the artificial is not affected, so that half the current goes through the artificial antennae.

With the high-frequency alternator method, reducing the waves for telephonic purposes, the Brant Rock station has talked with Jamaica, N.Y., 200 miles away. The tower has eight 300-ft. cages spread out in umbrella shape, with a radiation resistance of about 8 ohms. The energy radiated by the antennae in sending 200 miles was something over 700 watts. The current in the antennae was from 7·5 amp. to 8 amp. The total amount of energy expended, including the rather inefficient type of alternator used then, was about 7 h.p. The system is slightly more selective than the wireless telegraph in that in using the machine one has a very peaked wave. The tuning is very short on account of the pure sine wave, although its secrecy is not absolute. The only way that it could be changed would be by varying the speed at times. The quality of speech does not vary for the distance except in loudness.

A GAS-POWER 60-CYCLE TRACTION STATION

A GENERATING station of some interest, as being the first combined traction and lighting station in which 60-cycle alternators are driven in parallel by gas engines running on producer gas obtained from bituminous fuel, has recently been put into operation at the small American city of Charlotte, N.C., and is described in *Power and the Engineer*. The station supplies some 26 miles of double-track street railway, 200 arcs, and about 12,000 incandescent lamps.

The producers are what are known as the Loomis-Pettibone down draught type, arranged in two sets, each comprising two

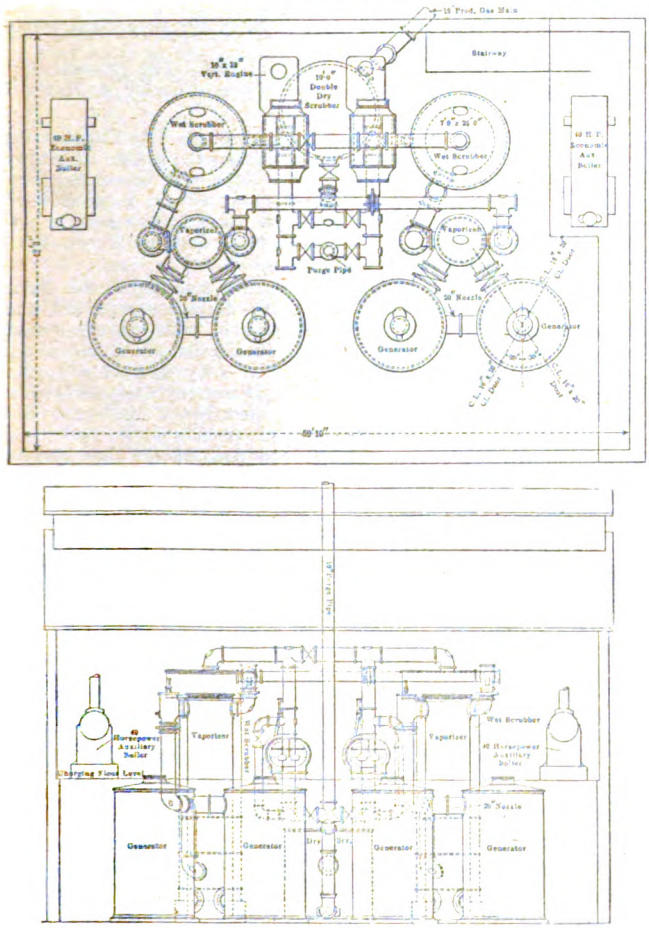

FIG. 1.—PLAN AND ELEVATION OF PRODUCER PLANT.

generators, a vapouriser, and a wet scrubber; a double dry scrubber, built in a single structure, serves the two sets. Each generator is 7 ft. in diameter and 14 ft. high. The two generators of each pair are connected permanently by a 20-inch nozzle at the extreme top of the shell, but each has its own outlet to the vapouriser, as usual. The vapouriser is a simple vertical boiler, 5 ft. in diameter, and 23 ft. high. The working steam pressure is 100 lb. per sq. in. The wet scrubbers are of the usual coke-filled type, 7 ft. in diameter and 26 ft. high, over all; on top of each one is the auxiliary dry scrubbing compartment. The double dry scrubber is 10 ft. in diameter and 5 ft. high. The arrangement of the producer plant is shown in Fig. 1.

The producers are operated alternately, one set at a time, until the vacuum gets up to about 14 in. of water; then the other set is put to work, and the dirty set shut down and cleaned. Under present load conditions this means shifting from one set to the other about every ten days.

The company operates also an illuminating-gas plant, which is in a building adjoining the power-producer house. The auxiliary boilers shown in the drawings supply steam to that plant and for driving the fan engines in both plants. The gas from the producer plant is led by a 16-in. main to a holder of 60,000

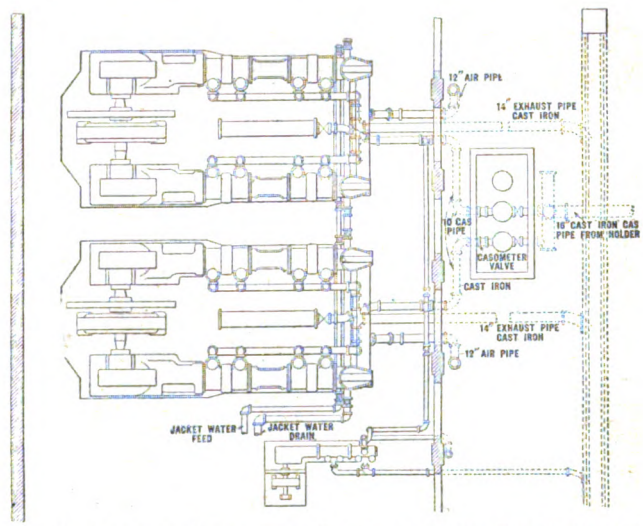

FIG. 2.—PLAN OF GENERATING PLANT, SHOWING PIPEWORK, &C.

cubic ft. capacity located near the power-house. From the holder a 20-in. pipe carries the gas to the power-house.

The power-house equipment at present comprises two twin tandem double-acting Snow engines with General Electric alternators each located between the two frames of its engine; a smaller Snow engine direct-connected to a direct-current exciter dynamo; a 40-kw. motor-driven exciter; two rotary converters for the railway system, and a little motor-generator for charging a set of storage batteries which supply ignition current.

The main engines are 24-in. diameter of bore, and 36-in. stroke. The speed is 120 revs. per min., giving a piston speed of 720 ft. per min. The engines are equipped with simple mechanically operated make-and-break igniters, which are supplied with current at 10 to 11 volts by a set of "Chloride" accumulators. The main generators are 3-phase machines of the usual revolving-field type; they deliver current at 2,300 volts and 60 cycles, and are rated at 540 kw. at 90 per cent. power-factor.

The motor-driven exciter is the one regularly used; it is a 40-kw. 125-volt dynamo, driven at 720 revs. per min. by a 60-h.p. induction motor, which takes current directly from the 2,300-volt bus-bars. The smaller engine cylinders are 12 in. diameter of bore, and 16 in. stroke; the exciter it drives is

Digitized by Google

of the same voltage and output ability as the motor-driven machine, but its speed is 260 revs. per min. This unit is only for emergency service. The rotary converters are of 300 and 500 kw. capacity respectively.

The switchboard is on a gallery at one end of the power-house. Fig. 2 is a plan of the equipment, and shows the arrangement of the apparatus and piping. Space has been left in the power-house for another unit, and in the gasometer-house for its intake connections.

The cooling water is carried from the engine jackets to a "hot well," from which a centrifugal pump takes it for delivery to a system of cooling sprays which deliver it to a surface pool. Another pump, of one-fourth the capacity of the spray-feed pump, takes water from the pool to the engine jackets. These two pumps are direct-driven by a single motor, and their relative work is therefore constant. The pool overflows into the "hot well," and as the spray pump works four times as hard as the jacket pump, the cooling water is circulated through the sprays four times as often as it passes through the engine-jackets.

The heaviest load the plant has been called on to supply was on a certain circus day, when 11,130-kw. hours were supplied during the day with a coal consumption of 16,795 lb., or 1·51 lb. per kw. hour. The overall efficiency of the engines has been determined from indicator cards at 80 per cent., and the only engine troubles recorded have been a broken oil-pipe, a little difficulty in governor adjustment at the outset, and an occasional back fire.

LOCAL NOTES

ACTON: *The Electricity Officials.*—As the result of recent happenings in connection with the electricity undertaking, which seem to have been greatly exaggerated by the local Councillors, both the Electrical Engineer and his chief assistant have been reprimanded. The form of the resolution passed by the Electricity Committee, and confirmed by the Council, was as follows: "The Committee, having thoroughly investigated the matters brought to its attention, is of opinion that the Electrical Engineer should be informed that the Committee regret that certain matters relating to his department should have happened, and that he be cautioned as to any repetition, and that greater care be taken by him in the management of the department in future." It was at first proposed to dismiss the assistant engineer, but the Council decided to treat both officials in the same manner.

The Position of the Electricity Undertaking.—Negotiations are to be continued with the Metropolitan Electric Supply Co. with a view to a lease of the Council's electricity undertaking.

BARNSTAPLE: *Electrical Repair Work.*—The Electric Lighting Committee have had a conference with their consulting engineer, Mr. W. H. Trentham, with reference to what powers it will be necessary to secure to authorise the Council to undertake the repair of consumers' motor and similar general work.

BELFAST: *Holywood Tramways.*—The Law Committee of the Corporation recommend that opposition be offered to the Bill of the Holywood Tramways Co., which seeks an extension of time for the carrying out of the works authorised in 1904. Under this latter Act the Corporation obtained powers to construct the portion of the line, viz., 1 mile, 3 furlongs, in the city, within 12 months of 1904. The company are now seeking an extension of time within which to put the undertaking into operation, and it is in order to secure that the extension, if passed, shall also apply to the line within the city, that opposition to the Bill is recommended.

Tramway Engines.—At the monthly meeting of the Corporation on New Year's Day, it was announced that the arbitrator between the Corporation and Messrs. J. G. White, Ltd., in respect of the tramway engines had awarded the Corporation the sum of £1,700. In the case of the other engines supplied by an English firm, it was found that part of the work had been done in Germany, and as the contract had not been completed in time, the matter had been referred to arbitration.

BERKHAMPSTEAD: *Electric Lighting Order.*—No opposition will be offered to the application by the Chesham Electric Lighting Co. for an electric lighting provisional order for this district by either the urban or rural district councils, terms having been arranged between the parties.

BOURNEMOUTH: *Tramway Expert's Report.*—The report of Mr. J. B. Hamilton, Tramway Manager to the Leeds Corporation, upon the matters raised in the Board of Trade report on the accident on the Bournemouth tramways in May last, has been received by the Corporation.

Mr. Hamilton recommends a reduction in the staff, and a rearrangement of the manner in which the stores are kept. He further recommends the reorganisation of the staff, and the appointment of new officers, including a General Manager at £600 per annum, an Electrical Engineer at £200 per annum, and a Rolling Stock Superintendent and a Traffic Superintendent at £275 per annum each. By this means he estimates a saving of £325 per annum. He further advocates the running of Sunday tram, and points to the possibility of a profit of from £4,000 to £5,000 per annum from this source.

BRISTOL: *Issue of New Stock.*—An issue is being made by the Corporation of £812,000 3½ per cent stock at £99 per cent. The proceeds of this issue are required for the repayment of debenture maturing on February 1st next, and also for the general purposes of the Corporation. It is secured upon the borough and general district funds and rates, and also upon the revenue of the dock and electrical undertakings of the city. The stock will be redeemed at par on July 4th, 1965, but may be redeemed at par at the option of the Corporation on or after July 4th, 1925.

BURNLEY: *Third-party Risk Reserve Fund.*—The Tramways Committee have recommended the formation of a special reserve fund to cover third-party claims, and that a contribution thereto for the first year of £600 should be made. This fund will meet claims for accidents, &c., not directly concerning the staff and employees, but the general public.

CARDIFF: *Tramway Men's Union.*—The annual meeting of the local branch of the Amalgamated Association of Tramway and Vehicle Workers was held on Sunday last. The balance-sheet for the year ended December 26th last shows an income of £360, of which £351 7s. 5d. was in contributions. Sick and accident allowances absorbed £105, funeral allowances £30, medical men's fees £28, special delegation and expenses £16 15s. The total expenditure for the year was £358 18s., including a sum of £105 remitted to the headquarters of the association. The balance at the end of the year was £96 15s. 6d. The membership of the branch is 380, an increase of 136 over 1907.

CHELTENHAM: *Electricity Accounts.*—It is announced that there has been a net profit of £2,691 upon the electricity undertaking for the past financial year.

CHORLEY: *Opposition to Tramway Bill.*—The Council have decided to oppose the Bill of the Preston, Chorley & Horwich Tramways Co.

DERBY: *Tramway Construction Penalties.*—The Corporation, in sending a cheque to Messrs. R. Blackwell & Co. in respect of the construction of the Ashbourne Road and Uttoxeter Road tramways, have deducted £1,573 9s. 2d., which, it is claimed, is due as penalties under the contract. A writ has been served upon the Corporation by the contractors, and the Town Clerk has been instructed to defend the action.

DONCASTER: *Tramway Rails.*—At the meeting of the Tramways Committee on Friday, the City Engineer reported that for stock and other purposes, 100 tons of rails were required, but that the Belgian firm who made their rails would not accept an order for less than 500 tons. The City Engineer further stated he had ascertained that the Doncaster Corporation required 200 tons of similar rails, and possibly, if an order were given for 300 tons, the makers would execute it on reasonable terms. In answer to questions, it was pointed out that English firms, when given the opportunity, had refused to cut a set of rolls to make the rail required. The rails in question have a 60-ft. length and a certain groove.

Halfpenny Tram Fares.—A proposal to institute halfpenny tram fares has been rejected by the Council by 14 votes to 2.

DUBLIN: *The Fire at the Town Hall.*—A short time ago considerable discussion took place as to the origin of a fire at the Town Hall, and we reported at the time that the Electrical Engineer, by stating that the current was cut off from the building when the fire took place, had disposed of the suggestion that the fire was electrically caused. Nevertheless, one doubting member of the Council is still not satisfied, and wishes the Local Government Board to hold a sworn inquiry "in consequence of the widespread belief entertained by the citizens that the recent fire at the City Hall was caused by electrical defects and negligence in the supervision of the electrical system in the building."

DUNDEE: *Charge for Tramway Current.*—With reference to the note in our last issue, with regard to the charge for tramway current in Dundee, we are informed that this matter has not come up for consideration by the Council.

EASTBOURNE: *Meter Rents.*—The Town Council have decided that for any consumer renting over 12 meters, the charge shall be reduced from 10s. to 6s. per annum for each meter, with the exception of double tariff meters.

FALMOUTH: *The Trackless Trolley System.*—The Corporation have an application before it for consent to the introduction of the trackless trolley system on certain specified routes. Should the reply of the Corporation be favourable, a detailed scheme will be presented, and an effort made to form a local company to finance the scheme.

HALIFAX: *Pye Nest Tramway Accident.*—The Tramways Committee has issued its final report regarding the cost of the Pye Nest tramway disaster. The total amount paid in com-

Digitized by Google

pensations amounts to £11,090, of which £1,000 has been paid by the Insurance Co., and £280 debited to the Workmen's Accident Insurance Fund. Only one case was actually taken into Court, but this was settled on its being called. The aggregate of the claims made was £15,819, exclusive of costs and doctors' charges.

HANLEY: *The Electricity Works Extensions.*—Mr. C. H. Yeaman, the Borough Electrical Engineer, has reported that the Deputy-Electrical Engineer, and two Charge Engineers, had worked a large amount of overtime, and rendered him valuable and energetic assistance in the extension building and constructional work which had been carried out during the spring, summer, and autumn in connection with the putting down of the new plant, steam pipes, and switch-gear. On the recommendation of the Electricity Committee the officials named are to be paid £10 10s. each for extra services rendered on constructional work. Alderman Coates, in moving the adoption of the report, said very efficient services had been rendered by these officials, and there had been a saving to the Corporation of between £100 and £200.

Electricity Accounts.—In his report upon the working of the electrical undertaking for the year to March 31st, 1908, the Borough Electrical Engineer, Mr. C. H. Yeaman, states that the total number of units sold was 1,472,520, of which 1,197,627 were for private supply and the remainder public lighting. The total receipts amounted to £15,970, and the expenditure, including capital charges, £14,641, leaving a net profit of £1,329.

HESTON AND ISLEWORTH: *Plans of Electric Mains.*—At the last meeting of the Urban District Council, the Electricity Committee reported that after the Local Government Board's recent inquiry, the inspector asked for a permanent set of mains plans on which the Council's existing mains were to be plainly set out. The maps required were to be 25 inches Ordnance Survey, and so arranged that they fold to foolscap size, the whole of the sheets being contained in a leather case. There are 15 sheets in all, and the cost of the complete set, with case, is £5 12s. The inspector explained that these maps are to be kept at the Local Government Board Offices, and that whenever required to enter up any extensions they would be sent back to the Council for revision. The Council authorised the necessary expenditure.

HUCKNALL-UNDER-HUTHWAITE: *Provisional Order Revoked.*—The Board of Trade has revoked the electric lighting provisional order granted to the Council in 1903.

HULL: *Electricity Supply in Hessle.*—The Town Clerk has reported upon the legal aspect of a request by the Hessle Council for a supply of electricity in their district by the Hull Corporation. At present the Hull Corporation only have powers to supply electricity to the Hessle Council in bulk, and if, as the latter desire, the Corporation is to work the Council's provisional order, which was granted in 1905, it will be necessary to obtain from the Board of Trade permission for a transfer of the powers under the order to take place. A special meeting of the Hull Electric Lighting Committee will be held to consider the position.

INDIA: *Lucknow.—The Indian and Eastern Engineer* states that the three years' concession for lighting the city of Lucknow with electricity, granted to a power company by the Municipal Commissioners, having lapsed, the Commissioners have addressed the Government asking its advice as to their undertaking their own electrical installation. If the reply is unfavourable, the Commissioners will invite tenders by advertisement for lighting the city by electricity.

Mussoorie.—Work in connection with the Mussoorie Electric scheme is making good progress.

ITALY: *Electrical Exhibition.*—With reference to the proposed electrical exhibition in Brescia in 1909, referred to on page 590 of our issue of October 29th last, we understand that the Associazione Elettrotecnica Italiana is taking action with regard to the arrangements, and especially for the reception of visitors.

LEEDS: *Officials' Salaries.*—One of the Councillors intends to move that the salary of Mr. J. B. Hamilton, the Tramways Manager, viz., £1,000 per annum, should be reduced to the level of that of the City Engineer, viz., £700.

LEEK: *Electricity Works Finances.*—In his report upon the accounts of the Council's undertakings for the year to March 31st, 1908, the district auditor states that the deficit of £709 15s. 5d. on the electricity account is a serious item, more especially in view of the further heavy capital expenditure to which the Council is committed. It would appear that the deficit is chiefly caused by the heavy cost of extensions for supplying power without an available compensating night-load—in other words, that the users of electric power are obtaining that power at a price unremunerative to the undertaking, and partly, therefore, at the expense of the general body of ratepayers. Both light and power are supplied at prices far below the maximum fixed by the Council's Electricity Order.

LEYTON: *Electric Light Consumers.*—There are now 2,000 customers of the electricity undertaking, an increase of 140 during 1908.

LIVERPOOL: *The Tramways and the Snowstorm.*—A report has been presented by the Tramways Committee dealing with the method and cost of clearing the snow last week for the tramway tracks. About 800 tons of salt were used, the approximate cost of which, together with the additional labour required, was £600. In addition, however, there was a decrease in the receipts of about £700.

LONDON: *St. Pancras: New Generating Machinery.*—The new 2,800-kw. 5,000-volt Willans-Dick Kerr turbo-alternator and 1,400-kw. Bruce Peebles motor-converter were taken over by the Council last week. The cost of the necessary buildings extension has been £5,448; the 25-ton travelling crane, £6,400; turbo-generator, £8,857; motor-converter, £6,180. The new machinery has been installed at the King's Road power station, where plant having a capacity of 4,000 kw. is at present at work.

Woolwich: "Linking Up."—At the last meeting of the Borough Council, a report of the delegates appointed to the deputation to the President of the Board of Trade with regard to giving powers to local authorities for linking up their electricity undertakings was considered. The Woolwich delegates did not attend with the deputation, as it seemed to them that the interests of their district were being ignored, and that only the Borough Councils in the north and east of London would reap any advantage. The Council confirmed the action of the delegates.

NORTHWOOD (Middlesex): *Street Lighting.*—The District Council have had under consideration two schemes for street lighting. From preliminary estimates submitted by the Northwood Electric Light Co. and the Pinner Gas Co., it appears that the cost of electric lighting would be £380 17s. per annum, or, under an alternative scheme, £317 11s., the price for gas being £387 19s. per annum, or £332 17s. under the alternative scheme. The report has been referred to a special committee for consideration, on the motion of a Councillor who refused to believe that electricity could possibly be cheaper than gas.

ORRELL: *Provisional Order Revoked.*—The electric lighting provisional order granted to the Council in 1903 has been revoked by the Board of Trade.

ROWLEY REGIS: *The Proposed Tramways.*—No further progress has been made with the negotiations for the construction of tramways between Rowley Regis and Quarry Bank. It will be remembered that Mr. C. S. Vesey Brown has been acting on behalf of a syndicate.

SIAM: *Imports of Electrical Goods.*—The value of the electrical goods imported into Bangkok for the year to March 31st, 1908, was £23,513. Of this, Germany supplied goods to the value of £11,255; Great Britain, £6,626; and Denmark, £2,950. The total figures for the two previous years were £8,732 in 1907, and £14,733 in 1906.

SOUTH AFRICA: *Bulawayo.—South Africa* states that there has been some misunderstanding between the Town Council and the Electric Lighting Company, who have a concession for lighting the town. The Council contends that failure to carry out the contract invalidates the concession, and has called upon the company to instal Osram lamps. This the company declined to do, and it may be found necessary to refer the matter to litigation.

SOUTH SHIELDS: *The Tyne Tunnel Scheme.*—The Parliamentary Committee have had under consideration the proposal, mentioned in our last issue, from the promoters of the North and South Shields Electric Railway, and also an interview between the Town Clerk and Mr. Schenck, one of the promoters. It had been arranged at the interview that Mr. Schenck should submit a proposal in writing, and the Council decided to defer consideration of the matter until this has been received.

Energy for Tramways.—The Electrical Engineer (Mr. J. H. Cawthra) has prepared a detailed report on an application by the Tramways Committee for a reduction in the price of energy supplied for tramway purposes. He points out that for the current year the tramways department will consume about 1,500,000 units, and at the present rate the average price per unit will be 1·36d., and the Jarrow & District Electric Traction Co. will pay 1·5d. per unit. This price compares favourably with the rates charged by other supply authorities selling energy under similar conditions. A reduction in price would mean handing over to the tramways department certain of the profits of the electricity department at the expense of the private consumer. The committee has decided to recommend the Council not to make the reduction asked for.

STOKE-ON-TRENT: *Water-cooling Apparatus.*—With reference to the Council's application for sanction to borrow £650 for the provision of a water-cooling apparatus at the Electricity Works, the Local Government Board has expressed the opinion that there was no necessity for this expenditure at the present time, and that the matter should be deferred pending the settlement of the details of the Potteries Federation Scheme. As the Electricity Committee are of the opinion that the matter is an extremely important one, a further application is to be made to the Board of Trade urging reconsideration of the matter.

SUNDERLAND: *Proposed Tramway Intercommunication.*—The Tramways Committee has received a suggestion from the Sunderland District Tramways Co. for mutual running powers over certain routes. Although the matter is under consideration, it is not thought probable, locally, that the Corporation will agree.

Digitized by Google

WATFORD: *Electric Wiring.*—The local electrical contractors are seeking to obtain an expression of opinion from the Corporation as to whether it is the intention to carry on wiring and fitting by the electricity department if the clauses to this effect in the Bill deposited for next session of Parliament are passed, or whether the work will be given out to contractors. The Electricity Committee have promised to make full inquiry into the working of such clauses in other towns before putting them into operation.

WEMYSS: *Tramway Receipts.*—For the year ended November 30th, the number of passengers carried by the Wemyss & District Tramways Co. was 1,834,023, an increase of 165,298 over those for the previous year.

WORCESTER: *Finances of Electricity Undertaking.*—The Electrical Engineer has reported an over expenditure upon machinery account of £720 through his having unfortunately under-estimated certain items. The Electricity Committee recommend that an application should be made to the Local Government Board for a loan to cover this and a few minor items of over expenditure.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRIA-HUNGARY. The *Board of Trade Journal* states that the municipal authorities of Szarvas (Hungary) have voted a sum of 400,000 kronen (about £16,700) for an electrical installation.

CARDIFF.—Tenders are invited for the electrical work in connection with the new factory of the Boston Collapsible Barrel & Manufacturing Co., including generating machinery, switchboards, and wiring. Particulars from the Superintendent of the Company, 79 York Road, London, S.E., fee £5 returnable, and tenders by January 26th.

HULL.—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £24,000 for the electrical undertaking.

LONDON: *Hammersmith.*—Tenders are invited for a 2,000-kw. steam turbo-generating set with condenser. Particulars from the Borough Electrical Engineer, fee £1 1s. returnable, and tenders by January 27th.

The engineer has reported that the extensions of machinery, plant, &c., necessary to meet the estimated increase in the normal requirements, and the estimated cost thereof, are as follows:—One turbo-generator, £7,500; condenser pipes and connections, £500; coal storage, No. 2 boiler-house, £1,200; forced draught, Nos. 2, 3, 4 boilers, £1,200; ventilator and cooler, £450; mechanical stokers, £600; circulating pump at wharf, £600; feeders, Tungsten Lamp Works, £1,463; transformers, £1,000; house services (new consumers), £2,500; small L.T. mains extension, £750; re-wind No. 8 alternator for two-phase, £350; contingencies, £1,358; total, £19,471. Steps are to be taken to put the proposed works in hand. The Finance Committee has passed an estimate of £2,025 for providing an additional main and machinery in connection with the supply of current to future exhibitions in Wood Lane.

TEWKESBURY.—The Tewkesbury Electric Lighting Co. invite tenders for the erection of a generating station. Particulars from Mr. C. W. Jones, Secretary, Tewkesbury, and tenders by January 13th.

WIMBLEDON.—Sanction has been given for the borrowing by the Council of £6,000, the estimated amount of capital expenditure upon electric lighting mains for the year ending March 30th next.

WORCESTER.—The Electricity Committee recommend that an application should be made to the Local Government Board for a loan of £4,000 for probable expenditure on mains during the next three years.

Miscellaneous

BIRMINGHAM.—The Guardians invite tenders for a telephone installation at the Workhouse, Western Road, Birmingham. Specifications from the Clerk, Parish Offices, Edmund Street, to whom tenders by January 14th.

FINCHLEY.—The Council has decided to adopt flame arc lamps for street lighting, and an application is to be made to the Local Government Board for a loan of £2,200, made up as follows:—50 arc lamps, including cable and fittings, £2,056; 34 extended bases to poles, £136; contingencies, £28. The Electrical Engineer estimates that the cost of maintaining 50 arc lamps of 3,000 c.p. each, including capital expenditure, would be £20 per lamp per annum, and the cost of maintaining 50 arc lamps of 2,000 c.p. each would be £18 per lamp per annum. He has provided in the estimate for fixing the arc lamps on top of the tramway centre poles where centre poles exist, and on top of the side poles in other cases, the lamp being alternately on either side of the road. In the case of side poles they will be attached to curved brackets.

HALIFAX.—Tenders are invited for miscellaneous stores for the tramways and electricity departments, including lighting fittings, electrical accessories, cables and copper wire, antifriction metal tubes and fittings, meters, overhead material and car accessories. Samples may be seen at the Skircoat depot. Tenders to the Town Clerk by January 20th.

ITALY.—The *Board of Trade Journal* states that the Italian Ministry of Public Works has granted to the Briantee Electric Tramways Co., Ltd., a concession for the construction and working of a line of tramway from Monza to Meda (Milan).

The Italian Minister of Public Works has, says the *Board of Trade Journal*, approved the form of the concession for a new line of tramway from Lodi to Piacenza, as definitely drawn up by the joint representatives of the Provinces of Milan and Piacenza, and the municipalities of Codogno, Castelpusterlengo, and Piacenza.

LONDON: *London County Council.*—Tenders are invited for the laying of stoneware cable ducts. Particulars from the Clerk, fee £2 returnable, and tenders by January 26th.

Camberwell.—The Borough Council invite tenders for various stores, &c., during the year ending March 31st, 1910, including maintenance of private telephones and electric bells, electric lamps, &c.

SPAIN.—The *Gaceta de Madrid* of December 16th contains a decree, granting to the provincial authorities of Guipúzcoa a concession for the establishment and working during 35 years of an inter-urban telephone system to link up the outlying districts of the above-mentioned province. For this concession the provincial deputation of Guipúzcoa will contribute to the State 10 per cent. of the gross receipts. The *Gaceta* may be seen by British firms interested on application at the Commercial Intelligence Branch of the Board of Trade.

YORK.—Plans and specifications have been prepared for the lines proposed under the Light Railway Order recently granted. These are to be submitted to the Board of Trade.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

PROVINCES.

BANFF (Scotland).—Conversion of Duff House into hotel (£20,000). Mr. Van Praagh, managing director, c/o De Wynter & Co., Charing Cross Road, W.C.

BECKENHAM.—Tenders are invited by the Urban District Council for electric wiring of houses in their district. Particulars from the Resident Engineer, fee £2 2s. returnable, and tenders to the Town Clerk by January 18th.

CALNE (Wilts.).—School. Architect, C. H. Smith, Chippenham.

CAMBRIDGE.—County school. Architect, H. Dunn, Sydney Street, Cambridge.

CORK.—Convalescent home. Architect, S. F. Hynes, Cork; builders, E. & P. O'Flynn, Cork.

ELTHAM.—Sunday school and mission hall, Elibank Road. Building Committee of "The Brethren," per W. H. Smith, 5 Great Winchester Street, E.C.

EXETER.—Mineral water factory. Surveyor, R. M. Challice, 14 Bedford Circus, Exeter.

GORTON (Manchester).—Church for Aspinall Wesleyans at Gorton, Reddish Lane (between £5,000 and £6,000). The Trustees.

HEXHAM.—Secondary school (240 places). Architects, Oliver, Leeson & Wood, Milburn House, Newcastle.

MIDDLETON (Lancs.).—School, Durnford Street (£15,394). Builders, J. Gerrard & Sons, Ltd., Long Street, Swinton.

MOTHERWELL (Scotland).—School (£12,500). Architect, James Cowie, 32 Brandon Street, Motherwell.

NORTH LOWESTOFT.—Technical schools (£9,000). Builder, Chas. Roper, Waterworks Street, Ipswich.

NOTTINGHAM.—New school at Trent Bridge (£9,995). Builder, J. Wright, Wilford Crescent East, Nottingham.

SHANKLIN (I.O.W.).—Kursaal. Architects, Frank Matcham & Co., 9 Warwick Court, W.C.

SHEFFIELD.—Sanatorium for consumptives at Tuxford, North Nottinghamshire, for Sheffield City Council. H. Sayer, Town Clerk.

SOLIHULL (Warwick).—Isolation Hospital (£8,240). Architect, W. H. Ward, 30 Paradise Street, Birmingham.

WARRINGTON (Lancs.).—Administrative hospital block at Sankey. T. Longdin, Borough Surveyor.

WOLVERHAMPTON.—Council school (£3,673). Builder, F. J. E. Tooby, 1 Castle Street, Wolverhampton.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Victorian Postmaster-General's Department has accepted the tender of Messrs. W. T. Henley's Telegraph Works, Ltd., Melbourne, for three miles vulcanised india-rubber cable, at £73 per mile.

The Queensland Postmaster-General's Department has accepted the tender of the Western Electric Supply Co., Ltd. (R. B. Hungerford, agent, Sydney), contractors for the Brisbane common battery switchboard, for the supply, at £279 10s., of apparatus necessary for electric current at a pressure of 220 volts, in place of the apparatus contracted for as required for current at 110 volts. This change has been found necessary consequent on the Brisbane Electric Supply Co. having decided to supply all current from January next at a higher voltage.

The Electric Supply Committee of the Melbourne City Council has recommended acceptance of the following tenders:—250 electricity-recording meters, Reason Mfg. Co., Ltd., £325, f.o.b. (London); 350 do., Siemens Bros. Dynamo Works, Ltd., £994 15., f.o.b. London; 170 do., Allgemeine Elektricitäts Gesellschaft, £233 15s., f.o.b. (Hamburg); 125 indicators, delivered at Electricity Supply Station, Australian General Electric Co., £130 7s. 6d.; 32 indicators, f.o.b. (London), Reason Mfg. Co., Ltd., £62 16s.; 100 spare boiler tubes, £1 10s. each, Babcock & Wilcox, Ltd.—(*Australian Mining Standard.*)

BEDFORD.—As the two Wilkinson feed-water heaters which were fixed to two boilers as a trial have given satisfactory results, they are to be purchased for £56.

HANLEY.—Tenders have been accepted by the Electricity Department as follows:—Cables, the British Insulated & Helsby Cables, Ltd.; bitumen, the British Electrical Trades' Supply & Bitumen Co.

HULL.—Tenders have been placed with the Rees Roturbo Manufacturing Co., Ltd., and Messrs. Siemens Bros. & Co., in connection with the electricity works extensions.

LEYTON.—The Council reveived the following tenders for a commutator for one of the smaller lighting dynamos:—Westminster Engineering Co., Ltd. (accepted), £43; India Rubber, Gutta Percha & Telegraph Works Co., Ltd., £60; Mather & Platt, Ltd. (makers of the machine), £113.

LONDON: *Southwark.*—The tender of Messrs. Alfred Blackmore & Co., at 11s. 4d. per ton, has been accepted for 6,000 tons of Griff or Kingsbury Peas for use at the electricity works.

Woolwich.—The Council received the following tenders for the supply of cast-iron pipework required in the construction of the cooling pond at Plumstead electricity works:—Aiton & Co., £160 6s.; John Spencer, Ltd., £167 10s. 3d.; Seagers, Ltd. (accepted), £169 10s. 6d.; Mackenzie & Moncur, £202 13s. 5d.; Ledward & Beckett, £255 17s.; Fraser & Chalmers, £407 17s.

ORIENT STEAMSHIP CO.—The orders for switchboards for the Orient liners now under construction have been placed with Messrs. Ferranti, Ltd., by the builders, viz., Messrs. John Brown & Co., Ltd., and the Fairfield Shipbuilding & Engineering Co., Ltd.

SALFORD.—The Tramways Committee have accepted the tender of J. Gerrard & Sons, Ltd., at £346, for the erection of a water-tower at the central car depôt. For carrying out the additional electric lighting installation in the car-fitting shops, &c., the tender of G. Hill & Co. has been accepted at £93 15s.

WATFORD.—The following contracts in connection with the electricity department have been sealed: Mr. L. R. Enser, buildings and flues; Messrs. Ashworth & Parker, fan engine; Messrs. J. Blakeborough & Sons, pipes.

Single-phase Traction.—The following are some of the lines now being equipped electrically on the single-phase system: The Padua-Fusina Railway in Italy, 21·7 miles long, with a contact wire pressure of 6,000 volts, and a frequency of 25 cycles; the rolling-stock will consist of ten motor-cars, each equipped with two 80-h.p. motors. The Lötschbergbahn, in Switzerland, is to be operated at 15,000 volts, 15 cycles; one locomotive with two 800-h.p. motors will be used on this line. The above equipments will be supplied by the Allgemeine Elektricitäts-Ges., who have also received a repeat order for 25 cars for the Blankenese-Ohlsdorf line. The Wiesenthalbahn, between Basel and Schopfheim in Baden, 34 miles in length, is being equipped by the Siemens-Schuckert-Werke for operation at 10,000 volts, 15 cycles; 10 locomotives, each provided with two 450-h.p. motors, will be supplied.

Telegraph Traffic.—In consequence of the terrible earthquake in Messina and other Italian towns, telegrams from Sicily and the province of Reggio-Calabria were subject to delay on December 29th, and were only accepted at senders' risk. On the same day the cable between Malta and Zante ceased to operate, although the Malta-Pozzallo cable was not broken, and worked well with Catania. The cable between Messina and Malta gave out on December 30th, and finally on the 3rd inst. telegrams for Messina were not permitted to be sent, and telegrams for other places in Sicily were still subject to delay, and accepted only at senders' risk. At this date the cable between Catania and Malta was reserved only for messages for and from Sicily. Communication between Medan and Penang is restored once more. We learn that communication with Port Limon and Costa Rica is interrupted.

MISCELLANEOUS CITY NOTES

CITY OF LONDON ELECTRIC LIGHTING CO.—Warrants in payment of the half-year's interest to the 31st inst. on the £400,000 5 per cent. first debenture stock, and £300,000 4½ per cent. second debenture stock, have been posted.

STRASBURG ELECTRICITY CO.—The *Financial News* states that a general meeting of the shareholders of the Strasburg Electricity Co. has approved the new contract concluded with the municipality of that town, and has decided upon the creation of 4,250,000 marks new shares.

BRUSH ELECTRICAL ENGINEERING CO.—It is notified that the certificates for the £100,000 prior lien 5 per cent. debenture stock can now be exchanged for allocation letters and bankers' receipts at the offices of Messrs. Wheater, Cornwallis-West & Co., 5 Austin Friars, E.C.

ELECTRIC CONSTRUCTION CO.—The directors have resolved to pay the dividend on the seven per cent. preference shares for the year ended May 31st, 1908.

MEXICAN LIGHT & POWER CO.—The special meeting of the Mexican Light & Power Co., which was held in Montreal last week for the purpose of considering the leasing of the company to the Mexico Tramways Co., was prevented from coming to a decision on the matter, owing to a technical objection to the resolution dealing with the proposal. It is stated that the shareholders' committee, which is opposing the lease, has an overwhelming majority in its favour. The question, it is anticipated, will be decided at the annual general meeting, which is to be held in February or March.

LONDON UNITED TRAMWAYS.—The directors have resolved that a payment on account of the 5 per cent. cumulative preference dividend shall be made at the rate of 2½ per cent. per annum for the half-year ending the 31st instant (making 3¾ per cent. for the year). Although there has been an increase in the total traffic receipts, yet, having regard to the additional route mileage being worked, the receipts have not shown that expansion which the directors had anticipated. Moreover, the company has had to encounter severe competition, which has seriously interfered with the growth of traffic on the main routes. When the accounts are published to the shareholders in February next, it will be seen, we are informed, that the directors have exercised every possible care in keeping the working expenses well within bounds, and that the revenue account will doubtless show a balance sufficient to cover the full dividend on the preference shares for the whole year. The directors, however, feel that in view of the necessity for providing funds to meet future renewals, the strengthening of the reserve funds, which they had hoped would have been possible out of increased receipts, should, in the permanent interests of the preference shareholders themselves, be no longer delayed, and that for the present the payments on account of preference dividend should be limited to 2½ per cent. per annum. The directors hope the shareholders will realise that in thus adopting a conservative policy, the course now taken is dictated by the desire to maintain the financial soundness of the undertaking.

ALLIANCE ELECTRICAL CO.—The order of the High Court confirming the reduction of the capital of this company from £120,000 to £60,000, reads as follows:—"The capital of the Alliance Electrical Co., Ltd., and reduced henceforth is £60,000, divided into 47,500 5 per cent. cumulative preference shares of one pound each and 12,500 ordinary shares of £1 each, reduced from £120,000, divided into 70,000 5 per cent. cumulative preference shares of £1 each, and 50,000 ordinary shares of £1 each.

COMPANIES' MEETINGS AND REPORTS

LONDON ELECTROBUS CO.—The report for the period from July 15th, 1907, to October 15th, 1908, which was adopted at the meeting last week, stated that while the directors regretted the necessity of issuing debentures, they had had many difficulties to surmount in introducing and fostering a new enterprise which had been considerably retarded, owing to the great opposition it encountered at the beginning. Notwithstanding this, the company had shown, by certified figures, that the electrobus was a commercial success, each 'bus in commission earning an operating profit of £448 per annum. The company, the directors state, is the only motor-'bus undertaking that has published details of its operating expenses and earnings. Experience had proved to the directors the profitable earning power of the electrobus, and, with the necessary working capital to augment the fleet of 'buses, there was no reason why in the near future the shares should not be on the dividend list. It was to be remembered that the heavy establishment expenses consequent upon the introduction of a new enterprise would not recur. The electrobus was now established, and was acknowledged to be superior to the petrol 'bus, both by the public and the authorities.

SUNDERLAND & DISTRICT ELECTRIC TRAMWAYS CO.—The report for the year ended October 31st, 1908, shows a loss on the year's working, after providing for interest on the Prior Lien bonds and the First and Second Mortgage Deben-

Digitized by Google

tures, of £1,467, bringing the loss to date up to £13,823. The loss on the past year would have been reduced to about £950 had the company not had to deal out of revenue with two items which will not occur again—namely, the loss on Consol deposit released, and the costs of obtaining the abandonment order for the unmade portion of the line, and the transfer of the tramway into the company's name. All these formalities have now been completed, and the property is in the company's name. Compared with last year, the traffic receipts at Sunderland showed an increase of £1,964; the cost of working to receipts comes out at 66 per cent., as against 75·41 per cent. last year. After consultation with the committee appointed at the last annual meeting to consider the question of running a service of goods cars, the directors decided not to proceed further with this project; the initial expense of inaugurating a scheme of this sort was found to be much heavier than was anticipated, and its ultimate success problematical. During the year Prior Lien bonds have been issued at par for cash to the value of £6,000, and a further block of £3,000 has been deposited against a loan of £2,000. Since the close of the financial year this block of £3,000 has also been issued at par, and the loan paid off. It is hoped that not more than £10,000 of the £20,000 Prior Lien bonds authorised will have to be issued. The directors are of opinion that, taken altogether, the accounts show a considerably improved position, and that the undertaking is gradually pulling round. The improvement would have been greater still had it not been for the unfortunate strike in the shipbuilding industry which began in February and lasted until September 24th. At the meeting on Tuesday, the Chairman stated that whereas for 1907 the deficiency was £4,723, for 1908 it was only £1,467. Summing up the present position, he stated that the company's accounts were now clean and shipshape, and the unmade portions of their authorised lines had been finally and legally abandoned. With regard to the future, they could only hope that the results of the disastrous shipbuilding strike would soon pass away, and that trade in the locality would improve in the New Year. If so, he thought they could be certain that during the coming year they would meet the interest on the three debenture issues out of revenue, and have something over. If this were so, they would then have to consider dealing with their suspense account, the accumulated arrears of preference dividends, and the rearrangement and reorganisation of their capital generally. The directors had a scheme in mind to achieve these objects, but the time had not yet arrived for placing it before the shareholders.

TOPSHAM ELECTRIC SUPPLY CO.—The annual meeting was held on Friday last, when the report and accounts were adopted. The report stated that although in existence a little over two years only, it was found at the beginning of the present year that the premises occupied as a generating station were much too small. Consequently it was decided to remove to a larger and a more central building. This has enabled a more economical means of distribution and generation. The chairman drew attention to the remarkable strides the company had made during its short existence. The income from this (the third) year was rather more than three times that of the first year.

APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. John Telfer, Tramways Manager to Warrington Town Council, has been increased from £175 to £208 per annum. The increase is to date from June 3rd last.

Mr. A. C. Kelly, Assoc.M.Inst.C.E., has resigned from the position of Traction Engineer to the British Westinghouse Electric & Manufacturing Co., Ltd., in order to join the staff of the Buenos Aires and Pacific Railway Co. at Buenos Aires.

Mr. E. Kilburn Scott, who is returning to England, having resigned his position at the Sydney University, has been presented with a gold watch by the Yorkshiremen's Society in Australia.

Mr. T. A. Taylor, Huddersfield, has been appointed mains superintendent at a commencing salary of £130 per annum, rising by £5 a year to £150, of the Hammersmith electricity undertaking.

On January 4th, Mr. Ralph U. Bailey, Engineer-in-charge at the Summer Lane electricity works of the Birmingham Corporation, was married to Miss Lottie May Hunter, of Newcastle. The electricity works staff presented him with a handsome clock.

NEW PUBLICATIONS

"Science Abstracts, December, 1908." Section A: Physics; Section B: Electrical Engineering. (London: E. & F. N. Spon.) 1s. 6d. each.

"The Practical Electrician's Pocket Book and Diary for 1909." Edited by H. T. Crewe. (London: S. Rentell & Co., Ltd.) Price 1s.

"The British Astronomical Weather Almanac and Chart, 1909." By B. G. Jenkin, F.R.A.S. (London: R. Morgan.) 2d.

"Electric and Petrol-Electric Vehicles." By W. Poynter Adams. (London: Charles Griffin & Co.) 5s.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £66 5s. to £66 15s. per ton (last week, £66 to £66 10s. per ton).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Burmah Tramways Construction Co. is to be wound up voluntarily. Mr. W. R. Elston is liquidator.

A meeting of creditors of the Eldon Electric Co. will be held at 24 Grainger Street West, Newcastle-on-Tyne, on January 11th, at 3 p.m. Claims to the liquidator, Mr. W. Sparks, at the above address.

The creditors of the Aluminium Corporation, Ltd., are required to send in particulars of their claims to Mr. S. W. Hawkins, Basildon House, Moorgate Street, London, by January 30th.

The liquidator in the winding up of the British Electrical Equipment Co., Ltd., has been released.

The first meeting in the bankruptcy of George Sutcliffe, trading as George Sutcliffe & Co., Electrical Engineers, 22 Church Street, Abertillery, Mon., will be held on the 13th inst. at 11.30 a.m. at the Official Receiver's offices, 144 Commercial Street, Newport, Mon. The public examination will take place on February 3rd at 11.15 a.m. in the Town Hall, Tredegar, Mon.

FIRE AT MESSRS. DENNIS & CO.'S WORKS.—We are informed that the fire which occurred at the works of Messrs. W. F. Dennis & Co. in Antwerp will not make any difference whatever in the prompt execution of the orders in hand or fresh orders.

COMPANY MORTGAGES

VENEZUELA TELEPHONE & ELECTRICAL APPLIANCES CO.—Particulars of £30,000 prior lien debentures, created by resolution of December 1st, and secured by a trust deed, dated December 7th, 1908, have been filed pursuant to Section 10 (3) of the Companies Act, 1907, the whole amount being now issued. The above-mentioned trust deed has also been registered. Property charged—various telephone systems in Venezuela, the contract or concession granted by the Venezuelan Government, and the company's undertaking and property, present and future, including uncalled capital. Trustees, Premier Investment Co., Ltd.

SUFFOLK ELECTRICITY SUPPLY CO.—Particulars of debentures to secure not more than one-half the paid-up capital for the time being, created November 2nd, 1898, have been filed pursuant to section 10 (3) of the Companies Act, 1907, the amount of the present issue being £50. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees.

TORQUAY TRAMWAYS CO.—Particulars of £60,000 debentures, created November 26th, and secured by a trust deed dated December 8th, 1908, have been filed pursuant to section 10 (3) of the Companies Act, 1907. None of the debentures have yet been issued. Property charged—The company's undertaking and property, present and future, including uncalled capital. Trustees: L. B. Schlesinger and Sir Nathanael Nathan.

NEW COMPANIES

AUTO-CONTROLLERS.—This company was registered on December 24th, with a capital of £800 in £1 shares, to acquire from R. H. Pearson and E. G. Bryant the benefit of certain existing inventions relating to automatic switches or auto-controllers, to develop and turn to account the same, and to carry on the business of electrical engineers, manufacturers of and dealers in electrical machinery, fittings, and appliances, &c. The subscribers are R. H. Pearson, The Bungalow, Boscombe, Hants, engineer; E. G. Bryant, 6 Town Hall Avenue, Bournemouth, engineer. Private company. Table "A" mainly applies. Registered office, 4–5 Town Hall Chambers, Bournemouth.

ALUMINIUM FOUNDERS.—This company was registered on December 24th, with a capital of £2,000 in £1 shares, to carry on the business of metal founders, electrical and general engineers, &c. Private company. The number of directors is not to be less than two nor more than four; the first are C. K. Graham (chairman), and E. Farmer. Qualification 100 shares. Remuneration as fixed by the company. Registered office, Raglan Street, Wolverhampton.

BEATEN METAL CO.—This company was registered on December 24th, with a capital of £2,000 in £1 shares (500 pref.), to take over the business of manufacturers of art metal work and gas and electric light fittings, &c., carried on at 90 Bromsgrove Street, Birmingham, as the Beaten Metal Co., and to adopt an agreement with C. A. Cooke and W. G. Galley. Private company. The number of directors is not to be less than two nor more than five; the first are C. A. Cooke and W. G. Galley. Qualification 100 shares. Registered office, 90 Bromsgrove Street, Birmingham.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Dec. 31st, 1908

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

26,294/07, **Supports for Metal Filaments.** F. HARRISON. This invention consists in mounting the metal filaments of incandescent lamps by means of springs attached at both ends of each unsupported portion, so that the whole filament is entirely insulated from shocks. The springs may be of steel, nickel steel, or German silver, and should be coated at the ends with zirconium or other suitable material to prevent the filament touching the steel. Expansion of the filaments when hot is taken up by the springs, and sagging is thus prevented. Two claims, five figures.

27,034/07, **Arc Lamp.** W. J. DAVY. This specification relates to the Davy open type flame arc lamp with four converging carbons, which was described in ELECTRICAL ENGINEERING, Vol. IV., page 489. The carbons are mounted on inclined guide frames, and two centrally guided weights linked to the carbon holders pull the carbons down. The claims are for a special form of sliding non-rotatable holder, and the arrangement of the swinging carbon frame. A cut-out for use when a shunt coil is employed is also described. Three claims, three figures.

4,372/08, **Automatic Pressure Regulation.** FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. Compounded continuous-current generators, when working in parallel, have the disadvantage that fluctuations of the pressure in the circuit produce considerable variations in the currents through the machines. According to the present invention, this unstable state is utilised to obtain an automatic pressure regulation, in that the equalising currents between a machine to be regulated and a compounded machine in parallel with it are caused to influence the magnetic circuits of both machines. An over-compounded machine is put in parallel with the shunt generator to be regulated, and auxiliary exciting windings on the magnet-poles of the shunt generator are connected in series with the compounded machine. The circulating current will thus raise the pressures of both machines, and by suitably adjusting the number of turns in the two series windings, the pressure of the shunt dynamo can be made to keep constant over wide variations in load. The main generator may be excited separately by a compounded machine which is in parallel with the main machine. If the latter is an alternator, a suitable converter must be interposed between the two machines. Three claims, four figures.

7,328/08, **Arc Lamp.** ALLGEMEINE ELEKTRICITÄTS GES. This specification describes a method of extinguishing the arc in lamps of the converging carbon pattern, when the carbons have burnt down to their shortest permissible length. It consists in providing a permanent or electro-magnet on the cross-beam, so that as the latter descends, the magnet approaches and finally blows out the arc. Four claims, one figure.

12,682/08, **Arc Lamp.** ALLGEMEINE ELEKTRIQITÄTS GES. This invention relates to arc lamps with converging carbons, and has for its object the prevention of the fumes from the arc reaching the mechanism. It is proposed to arrange the carbons in two parallel planes, and not exactly opposite each other as is usual. Striking and controlling the arc is then effected by moving one carbon laterally or in a plane at right angles to the planes of the carbons by means of a slide on the economiser. This slide covers the slot in the economiser in all positions, and prevents the fumes from entering the upper portion of the lamp. Two claims, four figures.

13,136/08, **Compensating for Temperature in Meters.** O. SCHULZE. According to this invention the effects of temperature on the readings of electromagnetic instruments provided with Foucault brakes are compensated for by varying the width of the gap of the magnetic circuit. This variation is effected by means of one or more closed hollow cylinders, each of which is fitted with an expansible membrane at one end. The membranes influence the position of one of the pole faces, which thus alters as the medium in the cylinder contracts or expands. One claim, four figures.

16,910/08. **Electrolytic Prepayment Meter.** E. SCHATTNER and R. AMBERTON. In the meter described in this specification a displacer, which carries one of the electrodes, is lowered into the electrolyte a definite amount when each coin is inserted. The rise in the level of the electrolyte is far greater than the amount of fall of the displacer, owing to the size of the latter. When the level of the electrolyte falls below the level of one electrode, the lamps are dimmed as the current passes through an auxiliary electrode and a resistance. Three claims, five figures. This meter was described and illustrated in ELECTRICAL ENGINEERING, Vol. IV., page 140.

19,311/08. **Manufacture of Metal Filaments.** SIEMENS AND HALSKE, AKT.-GES. According to the process described in this specification, nickel tungstate is mixed with tungstic acid or some plastic tungsten compound, so that after reduction by heating to a temperature of about 1,650° C. in an atmosphere of hydrogen the final alloy contains about 12 per cent. of nickel and 88 per cent. of tungsten. This alloy or intimate mixture of nickel and tungsten is ductile, and can be drawn or rolled. After the drawing the nickel is expelled by heating the filament electrically in a vacuum. Three claims.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: RENSING, 16,797/08; ALLGEMEINE ELEKTRICITÄTS GES., 17,535/08.

Dynamos and Motors: TYSON-WOLF (*Tyson-Wolff*) [Mounting of commutators] 28,044/07; CROMPTON & CO., MACFARLANE AND BURGE [Motor-generators] 3,626/08; LJUNGSTRÖM, 6,955/08; SIEMENS-SCHUCKERT-WERKE [D.C. machines] 11,517/08; SIEMENS BROS. DYNAMO WORKS (*Siemens-Schuckert-Werke*) [Cooling of end-connections] 17,416/08; REINEKE, 17,936/08.

Electrometallurgy and Electrochemistry: COWPER-COLES [Hydrogen and oxygen generators] 14,285/07; ALEXANDER, MCCLELAND AND LANGE [Unstable solutions] 27,463/07; HORNBLOWER [Galvanising apparatus] 28,664/07; LONDON ELECTRON WORKS CO., and DE BACK [Recovery of tin from scrap] 17,115/08; MARSH [Furnaces] 19,265/08; KELLER [Furnaces] 21,741/08.

Ignition, Electric: HALL [Magneto machine] 16,848/08.

Incandescent Lamps: ALLGEMEINE ELEKTRICITÄTS GES., 28,138/07; PLANCHON, 4,956/08.

Instruments and Meters: HOOKHAM and HOLDEN [Prepayment meters] 2,769/08; EVERSHED & VIGNOLES, LTD., and VIGNOLES [Resistances for potentiometer measurements] 12,296/08; SIMMANCE and ABADY [Recording mechanism] 13,018/08; KENNEDY [Alternating-current integrating meters] 17,730/08.

Switches, Fuses and Fittings: HOPE [Combined switch and fuse] 27,582/07; MUNDLER [Globe galleries] 7,740/08; MORGAN [Connectors] 7,855/08; STRANGE [Switch lock] 11,355/08.

Telephony and Telegraphy: ORT, RIEGER and ORT [Instruments] 27,453/07; CARDWELL [Telegraph typewriter] 28,736/07; KINGSBURY (*Western Electric Co.*) [Switching apparatus] 197/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) [Relays] 7,730/08; GIBBERD and ELIAS [Disinfection of mouthpieces] 17,612/08; PALMBORG [Automatic exchanges] 17,934/08.

Traction: SIMPSON [Brake blocks and collector shoes] 1,178/08; VOSS [Slipper brake] 1,428/08; MALEY and COCKSHOTT [Brakes] 1,981/08; STONE and QUILLIAM [Lubrication of journals] 6,750/08.

Miscellaneous: HUMPHREY [Hot-plates and ovens] 2,807/08; TORRINI, HOFFMANN and BENOIT [Substitute for ebonite] 10,731/08; SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckert-werke Ges.*) [Electromagnetic clutches] 16,766/08; LUITHLEN [Interior illumination without shadows] 18,508/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Ignition, Electric: SOC. D'ELECTRICITÉ NILMELIOR, 24,241/08.

Incandescent Lamps: SIEMENS & HALSKE AKT. GES. [Tungsten filaments] 25,854/08; KROLL AND SAKLATWALLA [Filaments] 27,144/08.

Miscellaneous: SCHRÖTER [Attachment of wires to insulators] 27,075/08; SIEMENS-SCHUCKERT-WERKE GES. [Covering fine wires] 27,097/08.

Expiring Patent

The following patent expires during the current week after a life of fourteen years:—

523 of Jan. 8th, 1895. **Lightning Arrester.** R. BELFIELD. This patent relates to a form of lightning arrester consisting of two metal strips, between which is a gap of a fraction of an inch, mounted on a base. The gap is bridged by a piece of charred lignum vitae, and the whole is covered with a perforated piece of wood.

HYDRO-ELECTRIC POWER IN SWITZERLAND

ACCORDING to *l'Electricien*, the Bill dealing with the control of water-power, proposed by the Swiss Federal Government, has received the sanction of the people by a large majority. The following is a translation of a section of the Bill in question.

The utilisation of water-power resources is placed under the supreme control of the confederation. The federal legislation will promulgate the necessary general regulations to safeguard public interests, and to ensure the proper utilisation of hydraulic power. The provisions will keep in view, as far as possible, the interests of navigation of the waterways of the country. Subject to these general regulations the control of the utilisation of water-power resources will devolve upon the cantonal authorities. In cases, however, where one section of a watercourse which is required for a power scheme passes through several cantons, and an agreement cannot be arrived at between the various cantonal authorities concerned, the confederation shall have the power to grant the concession direct. It shall also have the power, after hearing the views of the canton interested, of dealing with watercourses forming the frontier of the country. The royalties to be paid for the utilisation of water-power resources shall belong to the cantons or the party appointed by cantonal legislation. The confederation shall fix, after hearing the views of the canton interested and giving due consideration to their legislation, the amounts of royalties for all concessions granted direct, but the cantonal authorities shall, within the limits prescribed by the federal legislation, fix the royalties in the case of all other concessions. The supply of energy produced from water-power is not to be supplied to a foreign country without consent of the confederation. After the coming into force of this Act, future legislation shall only apply to new concessions. The confederation shall have the power to issue regulations for the transmission and distribution of electrical energy.

A NEW FORM OF BRUSH GEAR

THE accompanying illustrations show a new type of brush gear which has recently been designed by Mr. W. E. Vidal to obviate certain objections met with in some forms of brush holder in general use. Variation in size of carbons is met by a screwed-up contact grip giving a firm and easy pressure on the carbon. Between the carbon holder and the clamp fitting on to the dynamo brush arm is a flexible wire or strip, which is independent of any sweating or soldering. One of the chief features is the method of obtaining direct vertical pressure by means of a spring-controlled bell-crank lever, which bears on the forward end of the brush holder. This lever also acts as a detent for the brush holder in an "off" position, as is shown in the right-hand illustration. It will be seen that the

VIDAL BRUSH HOLDER.

spring is kept well away from the current-carrying parts, and is therefore well out of the way of heating effects. For small motor work no adjustment is given for spring tension, but in the designs for larger machines a tension screw is fitted at the back end of the spring. The carrier is prevented from touching the commutator by a small cross-bar at the back end of the moving portion of the holder, which bears on the fixed arm when the carbon has become sufficiently worn. A further point is that owing to the fact that all parts are brass castings, no expensive dies are necessary for stamping, and the maker, Bertram Thomas, of Manchester, is therefore able to turn out this particular form of brush holder at a very inexpensive rate as compared with many other brush gears on the market.

Electric Heating in the Textile Industry.—An interesting application of electric heating is described in a recent issue of the *Elektrotechnische Zeitschrift*. In the process of dressing cloth, it is necessary to heat it under pressure, and it is usual to do this by means of steam-heated presses. In the system described, the usual boards are interleaved with the cloth to be pressed, and insulated woven resistances are inserted at intervals of one to two inches. These resistances or heating grids can be obtained for pressures between 40 and 120 volts, and are carefully insulated to prevent all risk of fire. The cost of this method of heating works out somewhat higher than that of steam heating, in spite of the higher efficiency obtained, but against the higher cost are to be set the possibility of easy regulation of temperature, the cleanliness, and the even heating through the mass of cloth under pressure.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

SIMPLEX CONDUITS.—A booklet is being issued which, under the title of a year's progress, describes the advances and expansion of the numerous departments and branches of the firm of Simplex Conduits, Ltd. It contains some typical illustrations of the special manufactures of the firm,, and a series of portraits of the managers of the various departments and branches.

METAL FILAMENT LAMPS.—A pamphlet to hand from Messrs. Marples, Leach & Co., Ltd., gives particulars of the "Admil" tungsten lamp, and transformers, adaptors, and other accessories for the same. These lamps are made entirely at the Bergmann Works, including the filaments, and a special feature is the use of a special chemical deposit within the bulb to prevent blackening of the glass. The method of supporting the filament makes them able to run satisfactorily at any angle. They are made in a variety of sizes, from 3 to 100 c.p., and for voltages from 6 to 260.

REFLECTORS AND SHOP WINDOW LANTERNS.—The Sun Electrical Co., Ltd., of Charing Cross Road, have issued a leaflet with particulars of several forms of their well-known "Sunlite" lineal reflector fittings, both for carbon and metal filament lamps, and some new forms of outside reflector lantern for shop windows and similar purposes.

PYROMETERS. A leaflet describing several forms of the Vulcan thermo-electro pyrometer is being issued by Messrs. W. Geipel & Co. Recording as well as indicating patterns are included, suitable for various ranges up to 1,600° C.

TELEGRAPH APPARATUS.—The new catalogue of telegraph apparatus of British Insulated & Helsby Cables, Ltd., is an excellently printed production, particularly as regards the illustrations. A considerable variety of telegraph and telephone instruments are illustrated, including not only a large number of pieces of apparatus which are now practically standardised for telegraph work and several special appliances of the company's own design. Attention should be drawn to the Vyle polarised sounder and the telegraph line test-boards, distributing cabinets, &c. The telephone section includes the pantaphone, an instrument for use on short telegraph circuits, the Collier Marr receiver, suitable for use on vibratory superimposed telegraph circuits, and a view of a multiple telegraph switchboard is also given.

POCKET-BOOKS, DIARIES, &c. for 1909.

The D.P. Battery Co.'s wall calendar is always an artistic production; this year it includes an excellent photograph of the company's picturesquely situated works at Bakewell, in Derbyshire, taken from the dam which serves the water-wheels driving the works.

Messrs. Callenders' Cable and Construction Co. have chosen a handsome coloured picture of H.M.S. *Indomitable*, on board which warship the main electrical distribution is effected by means of their cables and special boxes for the adornment of their artistic calendar for 1909.

We have received from Messrs. Simplex Conduits, Ltd., a large diary, interleaved with blotting-paper, containing advertisements, not only of "Simplex" productions, but also those of other firms.

The well-finished daily calendar and memorandum pad now issued by the General Electric Co. is conveniently arranged to stand upon a writing-table, with the polished board upon which it is mounted, at a suitable angle. The name of each day is given in four languages, and ample space is left for memoranda, notes of engagements, &c., on the lower part of the tear-off sheet. A remarkably ingenious card accompanies the calendar in which the words, "The Osram Lamp" are only visible when looking through a special coloured screen.

A monthly tear-off sheet calendar, which is exceptionally clearly printed, is to hand from Messrs. J. Halden & Co., of 8 and 9 Great Chapel Street, Victoria Street, the well-known specialists in drawing office supplies.

We have received from Messrs. Johnson & Phillips, Ltd., of Charlton, a glass paper-weight, containing an effective representation of a section of a large triple concentric lead-covered armoured cable.

An artistic coloured calendar card forms a supplement to the current number of "Installation News," issued by Messrs. Simplex Conduits, Ltd.

The Bolt Head Wireless Telegraph Station.—According to the *Standard*, communication has been established between the new G.P.O. station at Bolt Head, and Scheveningen, in Holland, a distance of 375 miles. Messages have also been exchanged between the Dutch postal authorities, who have owned a Marconi station for some years, and the new G.P.O. station. The equipment of the Bolt Head station was fully described in ELECTRICAL ENGINEERING, December 17, page 717.

SOME ELECTRICAL COLLIERY EQUIPMENTS INSTALLED DURING 1908

THE following particulars relate to some of the more important electrical colliery installations, &c., which Messrs. Siemens Brothers' Dynamo Works, Ltd., have carried out during 1908.

The Cardiff Coal Washeries were erected some time ago on a site near the Queen Alexandra Dock, Cardiff, by Messrs. Franz Meguin & Co. for the Cardiff Washed Coal Co., Messrs. Siemens Brothers' Dynamo Works, Ltd., supplying the generating plant and motor and lighting equipments. The power equipment consists of a three-phase standard alternator having an output of 550 k.v.a., 500-525 volts, 50 cycles, at a speed of 125 r.p.m., the steam engine being of the tandem compound single-crank type. No separate fly-wheel is provided, as the necessary fly-wheel effect is obtained by providing sufficient weight in the rotor. The exciter armature is direct-coupled to the engine shaft, and the magnet frame is mounted upon a separate soleplate. No exciter bearing is provided. The power section of the main switchboard consists of one generator panel, together with two spare blank panels for extensions. Two feeder panels are provided, arranged for three feeder circuits of 400, 200, and 50 amperes capacity respectively. From the 400 and 200 ampere feeder circuits, three-core paper-insulated lead-covered cables are taken to distribution boards situated in different positions in the Coal Washeries. The 50-ampere feeder circuit supplies current to a 30 b.h.p. three-phase motor, which is direct coupled to a centrifugal pump supplying circulating water to the condensing plant beneath the engine-room floor. The starter for this motor is mounted on the switchboard, so that the motor can be controlled without the attendant leaving the switchboard platform. A passage-way is provided at the back of the main switchboard, and the ends are enclosed with expanded metal screens. The distribution boards in the washery are also arranged in the same manner, and are fitted with voltmeters and the necessary switches, fuses, and ammeters for controlling the supply to the following motors:—One conveyor motor, 12 b.h.p., 1,000 r.p.m.; one elevator motor, 25 b.h.p., 1,000 r.p.m.; one motor driving elevator and screens, 40 b.h.p., 750 r.p.m.; one motor driving elevator, 80 b.h.p., 750 r.p.m.; one motor driving drying plant, 80 b.h.p., 750 r.p.m.; one motor for washery, 80 b.h.p., 750 r.p.m.; one pump motor, 80 b.h.p., 600 r.p.m., for direct connection to shaft of centrifugal pump; and various other motors.

As the 20 b.h.p. and 12 b.h.p. motors are installed at some distance from the distribution board, these machines are provided with switch boxes (mounted near the motors). A 75 kw. belt-driven continuous-current generator supplies the lighting.

Another interesting application of electrical driving is to be found at Caer Bryn Colliery. The equipment supplied for this colliery consists of main switchboard, overhead transmission lines and distributing cables, together with motor equipment for a continuous-current supply at 500-550 volts. The switchboard consists of one generator and two feeder panels, supported by stays from the wall, so as to provide a passage-way behind the board of the width required by the Home Office Rules. The space behind the board is closed at each end by expanded metal doors. The generator panel is of 75 kw. capacity, and the feeder panels are arranged for five circuits for 100 amperes maximum. A leakage indicator, consisting of milliammeter with two-way switch and resistance, is fitted on one of the feeder panels. Between the power station and the pit shafts transmission lines of bare copper conductors are provided, being supported by creosoted timber poles about 32 ft. long; these are fitted with oak cross arms for carrying the porcelain insulators. Lightning arresters of the horn type are provided at each end of each transmission line, and are connected to copper earth plates. An earth wire is run the whole length of each transmission line, being carried on an additional insulator on each pole. It is connected to copper earth plates near the power-house. The shaft cables consist of two single-core vulcanised bitumen double wire armoured cables, and the underground cables are of the twin-core type, insulated with vulcanised bitumen and single-wire armoured; a cable of a similar type to that used underground is also employed for supplying current to a pump motor in the drift, this cable being mounted on a stand and provided with suitable gear, brake, &c., for raising or lowering the cable to suit the position of the pump in the drift. A double-pole main switch with double-pole enclosed fuses in a water-tight cast-iron box is provided at the top of the drift for cutting off the supply of current to the drift pump motor. The distribution board at the pit bottom is equipped with double-pole switches and fuses in water-tight covers. The motor equipment consists of the following 500-550-volt continuous-current machines:—An open type, compound-wound motor fitted with belt pulley and slide rails, for driving a "Waddle" fan about 20 ft. in diameter. It is capable of a continuous output of 30 b.h.p. at 300 r.p.m. This set runs continuously day and night at full load. The motor is controlled from a panel fixed to the wall, fitted with single-pole circuit-breaker with overload and no-voltage releases, single-pole quick-break switch, fuse of the porcelain type, and ammeter. The starter is of the liquid type with short-circuiting contacts. The two pump motors are of the protected type, shunt wound, and fitted with commutation poles. They are mounted on slide rails and driven by belt. Each has an output of 18-24 b.h.p. continuously at a speed of from 500-1,000 r.p.m., the speed variation being effected by shunt regulation. The ventilating openings are fitted with special sheet metal covers to prevent dripping water from entering the machines. Two ventilated, shunt-wound motors, fitted with commutation poles, are employed for driving by belt the conveyor and sump pump respectively. Each is capable of developing 10 b.h.p. continuously at a speed varying from 350 to 750 r.p.m. by shunt regulation. They are controlled from panels similarly equipped to those for the pump motors. The protected compound-wound motor in the washery has an output of 20 b.h.p. at a speed of 750 r.p.m. All the motor frames and switchgear are earthed by being connected to the earthing wire carried on the poles of the overhead transmission.

The Harton Coal Co., for whom another installation has just been completed, obtains electrical energy from the Cleveland & Durham Electric Power Supply Co. Among the motors supplied and put to work last year are the following:—At St. Hilda Colliery: One 400 b.h.p. three-phase induction motor for a full-load speed of 295 r.p.m. on 5,500 volts, three-phase, 40 cycles, is direct coupled by a flexible coupling to a colliery ventilating fan. This motor is complete with rotor starter and high-tension control switch pillar. There is also one similar fan motor, having an output of 300 b.h.p. at a full-load speed of 262 r.p.m. At Whitburn Colliery has been installed one 350 b.h.p., 5,500-volt, three-phase induction motor, also driving a ventilating fan, and also five haulage motors of the ventilated type, with the ventilating openings and slip-rings protected against splashing and dripping of water, and the insulation specially impregnated to render it waterproof. Each of these motors drives a main and tail haulage rope through gearing. This haulage is used for removing the trucks from the working face to the main galleries, where they are taken on by another haulage set. This side track is about half a mile long, and mostly on a gradual incline upwards away from the working face. Each motor is capable of giving 60 b.h.p. for 1½ hours at a synchronous speed of 480 r.p.m. on 2,750 volts, three-phase, 40 cycles. Each motor is provided with an oil-immersed reversing controller with 12 steps each way, and a high-tension switchbox containing automatic oil switch, &c. For driving centrifugal pumps two 35 h.p. motors of the same type have been supplied. A 50 h.p. drip-proof motor with waterproof insulation has also been supplied for Boldon Colliery for driving a fan through belting.

Another interesting installation carried out during the year has been a power equipment consisting of continuous-current generators aggregating 465 kw., switchgear, transmission lines, and a number of motors varying from 260 h.p. downwards, together with a complete lighting installation including special water-tight wiring of a wharf sometimes submerged, at the rotary kiln cement works of Messrs. I. C. Johnson & Co. at Greenhithe. Messrs. Siemens Brothers' Dynamo Works, Ltd., have also recently equipped Messrs. Barker & Allen's rolling mill at Birmingham with motors ranging up to 215 b.h.p., and also secured an order for the equipment of this firm's new mill.

APPLICATIONS FOR ELECTRIC LIGHTING PROVISIONAL ORDERS

THE following is the complete list of applications made to the Board of Trade for electric lighting Provisional Orders for the ensuing session of Parliament:—Chesham (Extensions), Chesham Electric Light & Power Co., Ltd.; Chipping Norton, Chipping Norton & District Electric Light & Power Co., Ltd.; Cleethorpes (Amendment), Urban District Council; Dunfermline and District (Amendment), Corporation; Herne Bay, Urban District Council; Hindhead and District (Extension), Hindhead & District Electric Light Co., Ltd.; Holsworthy, Messrs. Christy Brothers & Co., Ltd.; Skelmorlie and Wemyss Bay, Skelmorlie & Wemyss Bay Gas & Electric Supply Co., Ltd.; Southampton (Extension), Corporation; Staines, Egham Electric Lighting Syndicate; Stourbridge, Urban District Council; Turton, Urban District Council; Walton-on-the-Naze, Coast Development Corporation, Ltd.

Alleged Death from Electric Shock.—The Chelsea Coroner held an inquiry on Friday into the death of W. J. Reeder, a labourer in the employ of the Underground Electric Railways Co. of London, Ltd., who was found dead inside one of the boilers at the Lots Road generating station. It appears that the deceased had been instructed to paint and clean the inside of the boiler, and as he was there for a longer time than usual he was searched for, when it was discovered that he was dead. Dr. Ross, of Cremorne Road, S.W., expressed the view very definitely that the man met his death from electric shock. The *post-mortem* examination revealed a charred mark under the right elbow about 1½ in. long, and from appearances the man had fainted whilst inside the boiler. From the preliminary evidence it would seem that the deceased had been working by the aid of an electric lamp, as the remains of one were found in the boiler. The Coroner stated that it was clear he must have expert evidence, and he therefore adjourned the inquiry.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A LETTER in our correspondence columns from Mr. A. A. Day, Chief Electrical Engineer, Bolton Corporation, takes up the question raised in an article on "Power Supply" by "A Pessimistic Correspondent" in our last issue. Letters of criticism on the same article are also published from Mr. A. H. Seabrook, Electrical Engineer, West Ham Corporation, and two other correspondents not unconnected with power supply who prefer to remain anonymous. Other letters also appear dealing with gas engines, the action of flame arc lamps, and electrically-driven ice-making plants. (Pages 27 and 45.)

EXTENSIONS have recently been opened to the King's Road Generating Station of the St. Pancras Borough Council. A new engine-room of a size sufficient to accommodate four 2,000 kw. sets has been built, and one Willans-Dick, Kerr turbo-alternator of this size has been put down, together with a 1,000kw. Peebles-La Cour motor converter and the necessary switchgear. Special features of the new building are the ventilation arrangements and the care which has been taken with regard to noise and vibration. (Page 31.)

A NUMBER of prominent men in the electrical industry have established themselves as a provisional committee for the formation of an "Electrical League" to watch over and further the interests of the whole electrical industry in this country. (Page 35.)

MR. J. B. Hamilton, General Manager of the Leeds Corporation tramways undertaking, has presented a detailed report upon the organisation and working of the Bournemouth Corporation tramways department. Mr. Hamilton recommends a re-arrangement of the staff, a reduction of the number of employees in certain departments, and a thorough re-organisation of the method of training drivers. A matter dealt with at great length is in relation to the controllers, the condition of which was the primary cause of the accident referred to above, and recommendations are made to prevent the recurrence of such a catastrophe. The reserve fund is also regarded as insufficient. If all Mr. Hamilton's suggestions are put into force, he estimates that a saving of £8,000 per annum will result. (Page 36.)

Digitized by Google

A PAPER by Mr. A. B. Gridley, of the Cleveland & Durham Electric Power Company, deals generally with the saving in capital and coal consequent upon the centralisation of electric power supply. The principle of co-operation between metallurgical and other works having a large surplus of waste heat in the form of exhaust steam or combustible gases and the power supply company is explained in the paper, and the satisfactory results obtained by this co-operation in the district round the rivers Tees and Tyne are mentioned. Finally, the problem of a satisfactory tariff is touched upon, and a curve showing the average price per unit obtained under the operation of a tariff of £4 per H.P. per annum and 0·25d. per unit consumed for different load factors is given. (Page 38.)

UNDER Electrochemistry and Electrometallurgy we give an account of a Girod Electric Steel Furnace at Aarau, in Switzerland, and also of the Scott Anderson furnace, a novel feature in which is the situation of a powerful electromagnet below the furnace to control the arc generally and to obtain full advantage of the heat of the incandescent gases surrounding the electrode. (Page 39.)

AN article on the Fuller induction motors describes some of the methods adopted in the construction of these machines. The arrangements used for starting the single-phase motors, which are wound three-phase, are mentioned, and finally some particulars of some polyphase cascade motors for driving rolling mills are given. (Page 40.)

FROM a Board of Trade return just issued, it is seen that there are now 2,464 miles of tramways and light railways in the United Kingdom, of which 1,620 miles are owned by local authorities. Of the total, 2,286 miles are worked electrically. There are 305 undertakings, of which 177 belong to local authorities and 128 to companies. (Page 45.)

A SHORT article describes an improvement in the Harrison Universal photometer. (Page 43.)

THE Board of Trade is to receive a deputation from the Bath Corporation relative to the proposed sale of the electricity undertaking.—An order has been issued by the Board of Trade revoking the powers granted the Somerset and District Electric Power Co. in 1903 to compete in Bristol.—A strongly worded letter has been received from the Local Government Board by the Maidstone Corporation dealing with the working of the electricity undertaking.—There is some conflict between the Manchester Highways Committee and the Postmaster-General on the question of overhead wires for telegraph purposes.—The Salford Electricity Committee has been summoned by the Salford Public Health Department for allowing the emission of black smoke from the electricity works chimney. (Page 46.)

TRANSFORMERS are required at Bray, a water softener at Derby, and a booster at Middlesbrough. Extensions are to be put in at the Swindon electricity works, and a considerable expenditure upon telephone communication is contemplated at Liverpool. The Hereford Council propose to spend £5,700 on water cooling and induced draught plant and cable extensions. (Page 48.)

A DIVIDEND of six per cent. is declared by the Dublin United Tramways Co., and 1½ per cent. by the City and South London Railway Co. (Page 50.)

AMONG the Patent Specifications published by the Patent Office on Thursday last was one by H. L. Tyson-Wolff for a method of mounting the commutators on the shafts of high-speed machines so as to permit of expansion of the former. A patent by the Allgemeine Elektricitäts Ges. relates to a tungsten filament lamp containing an iron resistance in series with the filament. It is stated that a filament thus protected can be run at an efficiency as high as 0·7 watt per candle without unreasonably shortening the life of the lamp. A process for the preparation of a particularly homogeneous plastic compound of tungsten for squirting filaments is described in a specification by E. J. Planchon. A specification by Siemens-Schuckert Werke Ges. relates to a method of exciting a variable speed interpole generator. Siemens Brothers Dynamo Works, Ltd., have obtained a patent for an electromagnetic clutch, and T. J. Rensing has one for a means of ventilating the globes of arc lamps. An arrangement for stopping the feed of carbons in flame arc lamps when they are nearly burnt out has been patented by the Allgemeine Elektricitäts Ges. A method of adjusting the torque in alternating-current motor meters is described in a specification by R. Kennedy. (Page 51.)

THE adjourned inquest upon the labourer who was found dead inside one of the boilers at the Lots Road Power Station of the Underground Electric Railways Co. of London on December 28th was held on Monday. The portable electric lamp with which he was working at the time—of American make, with an Edison screw socket lamp—was proved to have been defective, and the opinion of the doctor was that for some reason the deceased had fainted in the boiler and fallen on the lamp, receiving a fatal shock. This view was accepted by the jury, who returned a verdict to this effect. (Page 52.)

THE electrical nitrogen fixation process employed by the Badische Anilin und Soda Fabrik differs considerably from the original Birkeland and Eyde method. A long arc is caused to pass rapidly up a tube containing a spiral of wire, and air is forced in at the bottom of the tube through tangential nozzles. (Page 52.)

THE list of influential men who have formed themselves into a provisional committee with a view to the founding of an "Electrical League," compels serious attention to be given to the project. In an unnecessarily sumptuous booklet which has been issued, and the gist of the contents of which will be found on another page, the objects of the proposed League are set forth at great length and in general terms. Primarily it appears that the object of its founders is to create a body which, by its weight of numbers, can bring firm pressure to bear on the Government into modifying the restrictive legislation that has hampered the progress of the electrical industry. The promoters of the League also hope to adjust difficulties between the various sections of the industry, so that it may present a united front. The objects are praiseworthy, and the proposal must therefore be considered solely from the point of view of practicability. Will the League have sufficient organising power to effect what is suggested, and will it be in a better position than any existing institutions in the electrical industry to carry out this programme? Answering the second question first, there can be no doubt that the Institution of Electrical Engineers, whose membership is thoroughly representative of the whole electrical industry, would be better qualified to undertake this work. Unfortunately, however, successive Councils of the Institution have shown a marked disinclination to taking up any broad or semi-political issues. We had hoped that, when the Institution resumed its sittings after the summer vacation in 1907, at which time depression in the electrical industry had already entered upon an acute stage, some action would be taken to institute an inquiry, and to endeavour to suggest some remedial measures. Nothing of the kind was done, and no signs of any such movement have been given this

Digitized by Google

session. Other electrical associations would be in a less favourable position than the Institution of Electrical Engineers, for, in the first place, their numbers are less, and, secondly, their energies must always be mainly directed to furthering the interests of their own particular section of the industry, which must be at least narrower than those of the electrical industry at large. Moreover, experience has shown that joint action between such associations for their common good has always been difficult. Thus it would appear that, in view of the apparent apathy of the Institution of Electrical Engineers, a new association or league might do useful work, for even if remedies are not possible and the present sickness of the electrical industry must run its course, there is likely to be occasion for action by a representative body in another direction. It is pointed out in the last paragraph of the pamphlet referred to, that there is a probability that fiscal, social, and industrial questions will occupy a "prominent place in the practical politics" of the near future, and the opinion appears to be sound, although it is worded with unpleasant alliteration. To put it more definitely, when the time comes for fiscal reform, and the imposition of a protective tariff, a representative body will be needed to watch the interests of the electrical industry. A general tariff in which all classes of finished machinery were exempt from duty would, for instance, be a heavy burden on our industry. If the Institution of Electrical Engineers remained passive, in order to retain its reputation of being non-political, and there were no other influential body to take charge of the matter, the results might be disastrous. It can be allowed, therefore, that if the Institution of Electrical Engineers continues to impose the present limitation upon its sphere of action, there is room for a new body such as the "Electrical League," and we come to the consideration of whether a League, founded on the basis proposed, would possess sufficient strength to carry out its programme. The issue of the present pamphlet, which we presume will be spread broadcast, shows that its promoters are in earnest, for a considerable sum of money must have been contributed by them to render this possible. It is doubtful, however, whether with its extremely low subscription the League will derive sufficient revenue for really active work, for it will necessarily need a highly-paid permanent secretary, experienced in the organising of such movements, and the expenses in salaries, printing, and postages will be high if efficient results are to be obtained. If, however, there is a general response to the appeal for members, and the League shows that it is a thoroughly representative body, it is but reasonable to expect that grants would be made to it from the various electrical associations, and also an additional "war fund" would possibly be contributed to by the membership on emergency. On the whole, therefore, our readers might do worse than contribute their modest half-crowns in support of the present movement.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 14TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read :—"The G.B. System from a Tramway Manager's Point of View," by Stanley Clegg.

FRIDAY, JANUARY 15TH.

Northampton Institute Engineering Society.

5 p.m. Meeting at the Institute, St. John Street, Clerkenwell, London. Paper to be read :—"Proportionment of Armature Teeth," by H. K. Whitehorn.

SATURDAY, JANUARY 16TH.

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New Street, when the President, Mr. G. T. Wood, will deliver his address.

MONDAY, JANUARY 18TH.

Institution of Electrical Engineers: Newcastle Local Section.

7.30 p.m. Meeting at Armstrong College.

Royal Society of Arts.

8 p.m. Cantor Lecture I. :—"The Public Supply of Electric Power in the United Kingdom," by G. L. Addenbrooke.

TUESDAY, JANUARY 19TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology. Paper to be read :—"H.T. Aerial Transmission Lines," by J. Wilson.

WEDNESDAY, JANUARY 20TH.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. Meeting at 92 Victoria Street, London. Paper to be read :—"Modern Mining Switchgear," by J. F. Shipley.

CORRESPONDENCE

ELECTRICAL POWER COMPANIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read the article in your current number by "A Pessimistic Correspondent," and although he may have some cause to take up the attitude which he has done in the matter of the present position of electric power companies, I think he has painted the picture in hues that are far too dark. The present power companies are very largely in the position they are, in my opinion, from the following circumstances :—

The large expenditure of capital without the requirements of the district being fully understood, due to a very large extent to a too lavish expenditure on cables.

The innate conservatism of the average English manufacturer who is unwilling to try new things, and very sceptical as to anybody being able to supply him with power at a cheaper rate than he can produce it himself, seeing that he is generally in a considerable way of business. In addition to this he also generally, if he makes a change, wants terms so very much better than he can hope to produce himself that there is not a very large margin of profit if the supply comes from outside sources and has to be transmitted any distance.

No doubt the power companies suffer to a certain extent, owing to the more thickly populated districts having been closed against them by the municipalities having already obtained powers in these districts, but this is by no means altogether against them, as in the more thickly populated districts the number of services is very much greater than in the areas mainly covered by the power companies, and the services are a very considerable portion of the expenditure on mains, the cost of services compared with the revenue derived from any consumer being very high in the case of these thickly populated areas. In addition, the power companies have, in most cases, up to the present time, very little load except a power load, which, of course, does not extend much into the evening, or, if it does, in such small proportions as probably to be run at a loss.

I think your correspondent is altogether out of it in claiming the capital cost at £75 per kw. There is no necessity for the capital cost being more than half this amount at the outside, and if his figures are matters of fact then it goes to prove that the financial arrangements of the company have not been of the best. I do not think, however, that the cost of legislation in connection with such matters is one which can properly be put forward as responsible for the present position of the power companies, for although it is more expensive than necessary and the expense of obtaining powers ought to be reduced, still, to claim that such expenses have any material effect upon the capital expenditure

Digitized by Google

in connection with a power supply scheme is, to my mind, quite absurd. If the power companies have to supply with such a small margin that the necessary legal expenditure for obtaining powers makes all the difference between profit and loss, then it is not likely that the power companies will be able to obtain capital at a low rate, which is absolutely necessary for an electric supply to be carried on profitably. I think too optimistic ideas with respect to electric power supply have been to the front. Such supply can only be carried on in a very large way, the margin of profit being a very small one, and unless carried on on a sufficiently large scale the likelihood of profit is not great. At the present time the power companies, with one exception, are not supplying on a sufficiently large scale to enable them to pay a small profit. I see no reason, however, why the power companies should not succeed if the areas obtained have got a fair number of works of different kinds to be supplied, and where they have not inflated their capital account, either by going in for plant on too optimistic a scale, or in any other way. In all cases of electric supply it is of vital importance to keep a watchful eye on the capital expenditure.

Assuming that the capital cost is halved (£37 10s. per kw.), as mentioned above, and "A Pessimistic Correspondent's" own rate of depreciation, &c., is taken, the standing charges for each unit would be 0·21d., and taking the works cost, as he suggests, at 0·25d. per unit, this would make a total cost of 0·46d. per unit (load factor 40 per cent., distribution loss 20 per cent.).

To show that such an assumption as regards capital expenditure is by no means out of the question, my own station has a capital cost, including everything, of £43 per kw. installed, after having had the disadvantage of starting 14 years ago, and having had to scrap practically all the original plant.

In the case of my own town, substituting a 40 per cent. load factor, as suggested by "A Pessimistic Correspondent," and assuming that we get an average price of ¾d. per unit, we should then be able to show, after putting on one side 7½ per cent. for depreciation, &c., a 10¼ per cent. dividend on our existing capital, notwithstanding that, in our case, we have not the facilities for water or coal which a modern power company would presumably have.

I see no reason, therefore, why, with a load factor such as that mentioned by your correspondent, it should not be quite possible to sell at a handsome profit at ¾d. per unit, which, as an average, I should think was quite low enough to enable the power company to get a very substantial business together, providing the district of the supply was a suitable one.

In conclusion, and I must apologise for having trespassed so far on your space, I think there is no reason why a power company should not pay, but it will not allow of fancy dividends except in the case of a very large concern in a good district. Unless it is managed by those having a good knowledge of electrical supply and the capital account is kept low there will probably be no dividends at all, but this latter case is no reason for stating that electric power supply cannot be made profitable.

Yours faithfully,

ARTHUR A. DAY,
Borough Electrical Engineer.

Corporation Electricity Works, Bolton,
January 9th, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I am glad to take advantage of your kind invitation to make a few remarks on the above subject in reply to your "Pessimistic Correspondent," and I suppose it is because I am generally considered to be unduly optimistic, even to the extent of ruining any undertaking which is unfortunate enough to be under my care, that you sent it. You will observe that I am pretty well acquainted with my reputation.

As regards power companies, I am among the ridiculed few who have a firm belief in the eventual financial success of power supply undertakings on a large scale and at low prices. The reasons of their immediate non-success have been pointed out by your correspondent, and I think hardly anyone would deny his accuracy in this respect. They are, briefly:—

(1) Heavy initial Parliamentary expenses; (2) difficulty in raising capital, compelling them to pay high prices for plant and mains; (3) necessity for putting in large units and a comprehensive system of mains from the commencement; (4) antipathy of existing supply companies and local authorities in the area; (5) in several cases bad lay-out and design of power station and distribution of equipment. Use of small units in the initial stages; (6) absolute neglect of the selling end of the business.

As regards 1, 2, and 3, they can only be grown out of, and the difficulties are rapidly being eliminated, because increased business does not increase them except possibly in some isolated cases. Because of No. 3, I do not believe it to be possible for any power supply undertaking, making any provision at all for capital repayments or depreciation, to make both ends meet during the first few years, even with a most completely equipped and organised selling department. A large number of units must be sold, because of their necessarily low price, to realise £1,000 in revenue, and, furthermore, capital expenditure is totally different in the case of power supply, on account of its high load factor, as compared with lighting supply; in the case of the latter, capital expenditure can be cut down even at the expense of working costs, because of the short hours of working, whereas all plant and mains put down for power supply must be generally more substantial and immune from breakdown, and liberal capital expenditure must be made to save working cost. A turbine using 1 lb. of steam per kw. too much in order to save £5,000 in capital is an infinitely more expensive article if put on power supply than if working on a lighting system, so that I think it may be admitted that capital per kw. must be higher in a power supply undertaking than a lighting.

As regards No. 4, the difficulty is undoubtedly being disposed of, and many small concerns are realising the advantage of taking a bulk supply from the power companies. This would have been more quickly brought about by a competent selling organisation. No. 5 is what nine out of ten supply undertakings, company and municipal, have suffered from in their initial stages, and can only be overcome as the undertakings grow. I regard No. 6—*neglect of the selling end*—as one of the principal causes retarding the progress of the power companies, and preventing their obtaining in a short space of time sufficient business to ensure financial success. I am pretty well acquainted with the methods of several, and I would like to ask, How many realise that when they have generated and distributed electricity that they have only half supplied the customer with what he wants? How many realise that the customer wants, not electricity, but power? How many hire or sell motors and apparatus to their customers—carry out any constructional work for their customers? In other words, how many have a sales department worthy of the name? Other businesses with something to sell require a selling organisation, realising that it is no use making anything well and cheaply if its sale is neglected, and why purveyors of power should imagine that they can do what purveyors of other supplies find impossible is inconceivable.

I am aware that one or two companies do all this, but I believe that even in those cases it has been

Digitized by Google

carried out in such a way that the work done for consumers has been unremunerative, and the cost has had to be borne by the undertaking generally, with the result that such work has been discontinued or curtailed. It can be, however, and should be, made remunerative, though not perhaps in the early stages. A sales department, before it can do work for consumers, has to get them from among those factories existing in the area, and entice other factories to come in, by publicity, canvassing, the establishment of a vacant sites and factories bureau, negotiating rents and assessments, and innumerable other devices. Several power companies are doing something in this direction now, but they should have commenced it six months before they commenced supplying current.

Your correspondent's remarks as to a unit costing ¼d. at the power house and 2d. at the consumer's terminals is, of course, pure imagination, if the installation is anyhow decently laid out.

As regards his figures, £600,000 is altogether an unreasonable estimate for 8,000 kw. of plant and mains. An unfavourable case of capital expenditure is West Ham, which undertaking has cost £420,000 for 8,000 kw. of plant. The said expenditure is inflated because it includes a scrapped power house, a large amount of old type generating plant (some of which cost £8 per kw., excluding condensing plant and accessories), boilers capable of carrying a load of 10,000 kw., and buildings capable of housing sufficient boiler and turbine plant to carry a load of 18,000 kw. It includes mains, transformers (86 sub-stations), meters, &c. £400,000, therefore, and not £600,000, should represent at least 8,000 kw. of plant and mains. I should take for capital charges, including dividends, 7 per cent. on £400,000, making £28,000 per annum. I agree with £7,000 for general charges, making £35,000 per annum fixed charges. The load factor, based on units sold, I would take at 30 per cent., quite a low figure, giving at 6,000 kw. maximum load an output of 15¾ million units, which at £35,000 cost 0·53d. per unit.

I would accept the figure of 0·25d. for works costs, making a total cost per unit of 0·78d., including dividends.

I do not agree at all that the undertaking taken as an example would require to sell at 1·204d. per unit to make a profit. From your correspondent's own figures, capital expenditure is £600,000—Revenue (16,820,000 units at 1·204d.) = £83,000.

Operating Expenses.	
General Management and Establishment ...	£7,000
Works Costs at 0·25 on 15,820,000 units ...	17,500
Total	£24,500

Percentage to revenue, 34 per cent.

This is contrary to the actual results from electricity supply, where the percentage of cost to revenue is nearer 50 per cent., and an undertaking having a cost of 34 per cent. to revenue would pay a very big dividend and be considered a highly profitable concern, much more profitable, in fact, than it is customary to find among electrical concerns, even the most successful of which are not accustomed to making gross profits of 70 per cent.

Taking my figures we get:—

Capital	£400,000
Revenue 15¾ million units at 0·78d.	51,000
Operating Expenses.	
General Management and Establishment ...	£7,000
Works Cost at 0·25 on 15¾ million units ...	16,400
Total	£23,400

Percentage of operating expenses to revenue 46 per cent., a figure more generally reached in actual practice. ¾d. per unit is a very fair all-round selling price for a power company, and I believe that a great deal of profitable business can be done at that figure, and that it should cover total expenses and pay dividends after the first year or two of working.

There is a most important class of supply which your correspondent has left out of his calculations altogether, and which is becoming the most important load for large generating stations. I refer to electro-chemical and metallurgical processes, which are now accumulating next door to power stations or as near as they can get. Many of these industries are such that they can agree to being turned off or vary their load at various times of the day, according to the station load, and also can arrange to be the first to be shut down in case of emergency. With this class of load an 8,000 kw. station can run up to 8,000 kw. of load, and the same thing with regard to mains. I am negotiating several such supplies, and know that rates can be agreed upon satisfactory to both the supply people and the consumers. This oversight on the part of your correspondent quite upsets his estimate of running and total expenses, and at the same time, of course, will bring the average revenue below ½d. per unit, according to the amount supplied. I believe this class of load will prove of great value to large power-houses and enable them to obtain nearly a straight line load curve, and the power companies, whose stations are usually so situated that there is plenty of vacant land around them, will attract to the neighbourhood large factories carrying out electrolytic processes, and to whom cheap power is of the utmost importance.

Yours faithfully,

A. HUGH SEABROOK,
Engineer and Manager.

West Ham Corporation Electric Supply,
84 Romford Road, Stratford, E., Jan. 11th, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—You publish in your current issue an article contributed by a member of the electrical industry under the *nom de plume* of "A Pessimistic Correspondent." This gentleman has written you on the subject of power companies, and having regard to the example which he gives at the end of his article, and which presumably represents his views of power company affairs, his pessimism is not to be wondered at; for his figures, assuming they are intended to represent the position of what may be called the active power companies, are founded on entirely erroneous premises. Perhaps, therefore, you will be so good as to allow me a little of your valuable space in order that I may put your correspondent right as to his figures, and by so doing dissipate to some extent the gloomy atmosphere with which he has evidently surrounded himself.

Your correspondent commences by assuming a capital expenditure of £600,000 for an 8,000-kw. station. If this figure were reduced to £300,000 or £350,000, it would be pretty near the mark, and why a power company, particularly in its pioneer stages, should be called upon to set aside a depreciation rate averaging quite double that considered necessary by much older concerns is probably known only to your correspondent. A reasonable figure for depreciation would be 2½ per cent. Assuming the capital to be £350,000, and the rate of depreciation 2½ per cent., your correspondent's figure of £30,000 under this heading is at once reduced to £8,750, when the figures are fairly stated. For management expenses £5,000 should be ample, as against your correspondent's figure of £7,000. The loss in transformation and distribution, assuming the latter to be in the form of three-phase current, should not exceed 15 per cent., as against your correspondent's figure of 20 per cent. The latter figure exceeds the loss on the Manchester Corporation system, in spite of the fact that this system requires a large proportion of the supply to be converted into direct current.

Some companies have already a load factor of considerably over 40 per cent., but on the basis of your correspondent's figure the units sold, allowing a 15

Digitized by Google

per cent. loss, would be 17,870,000 with a load of 6,000 kw. But no one acquainted with power supply problems supposes that a power company considers an installation of 8,000 kw. to be finality; such an installation is, in effect, only a pioneer affair, and the fact that companies with a plant capacity of this order are now beginning to do more than pay their way, although only partially loaded, is an ample justification for their promotion.

Generating plant can now be obtained for £4 per kw., and with boilers at £2, switchgear at £1 5s., and buildings at £3 per kw., it is clear that plant extensions can be carried out at less than £12 per kw., while £10 per kw. is a liberal figure for mains and sub-station plant. This gives £22 per kw. for extensions over and above the initial installation, and it needs no further explanation to make it clear that having overcome the enormous difficulties which were met with at the outset, the future of power companies is far from being in the hopeless state which your correspondent would have us believe.

Figures, it is true, can be made to show anything, but if your correspondent's example be modified to bring it within the region of actual practice they will read as follows when the initial installation has a load of 6,000 kw.:—

Capacity of plant	8,000 kw.	
Capital expenditure	£350,000	
Units sent out of station	21,024,000	
Units sold (15 per cent. loss)	17,870,000	
Inclusive works cost at 0·25d. per unit generated ...		£21,900
Management		£5,000
Depreciation, 2½ per cent.		£8,750
		£35,650
Income, 17,870,000 units at 0·7d.		£52,100
Surplus available for dividend		£16,450

or close on 5 per cent. on the full capital; not a bad result under any conditions, and quite satisfactory having regard to the unreasonable and expensive opposition the companies met with in their early days from so many quarters.

When, however, a power company has developed into an undertaking of reasonable size, having regard to the area over which it has powers to supply, and has a load of, say, 20,000 kw., with an installation capacity of, say, 25,000 kw., the effect on the company's finances is most marked. Thus the additional capacity over and above 8,000 kw., having been obtained as shown above for £22 per kw., the capital will only be increased by £374,000, namely, to £724,000.

The output on the same basis as before will amount to 71,000,000 units, which, less 15 per cent., gives 60,350,000 units sold. The costs will run much as follows:—

71,000,000 at 0·20d.		£59,200
Management		10,000
Depreciation, 2½ per cent.		18,100
		£87,300
Revenue, 60,350,000 at 0·6d.		150,600
Surplus available for dividend ...		63,000

or 8¾ per cent. on the capital.

In my opinion, however, a much higher load factor can be looked for than that on which these figures are based; granted this will involve a lower average price, but nevertheless it will leave the power company with a considerably greater margin of profit than that indicated above. The fact is, Sir, that power companies at the present time are making excellent and steady progress even in the face of the unexampled trade depression under which the country has been suffering for the past twelve months; and in spite of the early mistakes made with regard to many of the companies due to various causes they are undoubtedly proving their worth and utility to many manufacturers, both large and small, whose works are situated outside the large towns. The pioneer work of the past few years is showing abundant signs of bearing good fruit, and there seems no reason to doubt but that in the near future electrical power companies will take their proper position as recognised and profitable fields for investment.

ANTI-PESSIMIST.

Manchester, January 11th, 1909.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—The article in your last issue by "A Pessimistic Correspondent" on Electric Power Companies invites criticism. There is not much to be gained by discussing an assumed case of an imaginary company, which could obviously never hope to pay if it spent £600,000 on a distribution system and power station of 8,000 kw. capacity only. The only hope for such a company would be the reduction of its capital by 50 per cent. In an industrial area containing collieries, engineering works, miscellaneous factories, and a fairly large lighting load, there would be no prospect of doing a profitable business unless current could be delivered at the consumer's terminals at a cost of 0·4d. to 0·5d. per unit, inclusive of interest and depreciation on capital. This figure can be achieved if the following three conditions obtain, viz.: An extensive, yet concentrated industrial area; sound engineering, and good commercial management.

It is true that many of the Power Acts obtained cover areas in which no profitable business could be done, however sound and good the engineering and commercial management might be, and the companies holding such powers are never likely to do much with them. Possibly your pessimistic correspondent has these in his mind. It is also true that some other companies, whose statutory powers cover satisfactory areas from the power point of view, owe their lack of success, or at any rate in part, to the fact that they have been badly engineered, and even more badly managed by individuals who have failed to grasp the intricate problems which have to be solved if the business is to be properly handled.

But unquestionably the most serious obstacle which has retarded progress has been the opposition of local authorities, the result of which can be seen in the frightful cost of legislation, and the hindrance to business progress. When powers were being obtained, perhaps thirty to forty Corporations and District Councils had to be fought, and subsequently, in towns where consents have had to be obtained, the "powers that be" have done everything possible to obstruct the supply of power to, maybe, their largest ratepayers, who much desired to take it. There are Corporations who still continue to run their own small generating stations who have refused to entertain bulk supply offers made on terms which would have saved the ratepayers several hundreds a year. Fortunately, there is another side to the picture. Some of the power companies are making steady but substantial progress, in spite of the serious difficulties—political and financial—they have had to face, and if a reduction of capital may be necessary to place some of them on a dividend-paying basis, this will be largely due to circumstances over which they have had no control (but which have been forced upon them owing to unwise legislation), and will, after all, only be a similar fate to that which has befallen other industries whose fortunes have varied. The success of the Newcastle Power Company, to which one is referred in such a discussion as this, shows what can be done when the all-round management is good, and there are at least some of the other power companies covering important industrial areas concerning whose future one may reasonably be optimistic, and

NOT PESSIMISTIC.

GAS POWER STATIONS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In reading the article in your issue of January 7th on "A Gas-Power 60-cycle Traction Station," I was much interested to learn that the only engine trouble had been a broken oil-pipe. However, on going a little farther into the matter, that fact became less surprising. The output of each set is given as 540 kw., and, as no overload capacity is mentioned, I take it that this is the maximum output. Assuming a generator efficiency of 95 per cent., and calculating on the figures given in the article, the mean effective pressure in the engine cylinders appears to be about 48·3 lb. per square inch. This would probably be obtained with a compression pressure of about 80 lb. per square inch, and a maximum pressure not above 150 lb. per square inch. These pressures are no greater than are met with every day in steam engines, so that such a gas engine ought to be just as reliable as a steam engine.

On the other hand, its over-all thermal efficiency is probably not much greater than that of the best steam engine, and since the capital cost of an engine per unit of output is, roughly, inversely proportional to the M.E.P. developed, the capital cost must be exceedingly high. Under these circumstances, it is difficult to see what is the advantage of the gas-engine plant.

The only advantage of gas engines over steam engines is their high thermal efficiency, and to obtain this it is absolutely necessary to work with high pressures throughout the cycle.

The following table will show where the engines described in your article stand, in this respect, in comparison with other well-known gas engines. The mean pressures given have all been calculated from figures given in articles in various technical papers, and all refer to the declared output, as stated by the makers. In certain cases, where only the b.h.p. of an engine was given, the mechanical efficiency has been assumed in accordance with the writer's experience, viz., for a four-stroke single-acting engine, 85 per cent., and for a four-stroke double-acting engine 80 per cent.

Maker.	Type of Engine.	M.E.P. developed. lbs./□".
Snow Pump Co. ...	4 stroke, D.A., horizontal, tandem	48·3
Westinghouse ...	4 stroke, S.A., vertical, tandem ...	67·0
Richardson Westgarth	4 stroke, D.A., horizontal, tandem	59·5
Crossley	4 stroke, S.A., horizontal, tandem	72·5
Allis-Chalmers ...	4 stroke, D.A., horizontal, tandem	72·5
Premier	4 stroke, S.A., horizontal, tandem, with positive scavenging	85·5
Beardmore	4 stroke, S.A., vertical (marine) ...	97·0

From this table it is evident that the designers of the engines in question have secured reliability at the expense of both efficiency and small capital cost. It would be interesting to know how long the plant has been at work, and what is the longest continuous run done by either engine. I enclose my card, and remain,

Yours, &c.,

GAS ENGINE.

(*For further correspondence see page* 45.)

EXTENSION TO THE GENERATING STATION OF THE ST. PANCRAS BOROUGH COUNCIL

THE new extension which has just been inaugurated at the King's Road generating station of the St. Pancras Borough Council is of interest as marking the latest steps of progress in central station engineering, of which a number of stages are marked by the nature of the generating plant put down in the Council's stations from time to time.

The original station in Stanhope Street was opened in November, 1891, and formed the first municipal station in the Metropolis. The plant was continuous-current with small machine units and a three-wire distribution, first at 2 × 110 volts and later at 2 × 440 volts. Four years later, in 1895, the King's Road station was opened, and before the present new extensions were added the plant included two 500-kw. A.E.G. three-phase alternators, driven by Browett-Lindley engines and a pair of Parsons 1,000-kw. turbo-generators, besides several continuous-current sets, driven by reciprocating engines. The continuous-current distribution has been maintained all through, and on the introduction of alternating-current generating plant, the necessary converting equipment was installed in sub-stations. Of late, however, the alternating section of the plant has been very heavily loaded, and for some months the sets just mentioned have been running practically continuously, without spare plant.

To meet the rapidly growing demand, therefore, the King's Road station has been enlarged by the construction of a new extension to the engine room of sufficient size to accommodate four 2,000-kw. turbo-alternators of the Parsons, Willans, or similar horizontal pattern. A general plan of the new part of the building is shown in Fig. 1, from which the position of the set that has been already put to work can be seen.

One of the most interesting points in connection with the design of the building itself is the arrangement provided for ventilation, a subject of growing importance in the design of engine rooms for generating plant of such high output for its size as is now available. Elaborate care has also been given to obviating all possibility of sound or vibration being transmitted to the outside. This is a question which has been especially prominent at St. Pancras on account of troubles and litigation in the past. The scheme finding favour in some quarters of ventilating each machine separately by forced draught arrangements has not been followed, but ample provision has been made for the natural ventilation of the engine room as a whole.

The large ventilator in the roof is especially worthy of notice as embodying some quite new features. The objects in view in its design were to provide a free outlet to the heated air in a direct upward direction to the sky, so that sound could in no way be transmitted to the surrounding neighbourhood, and at the same time to afford complete protection from rain. The construction of the ventilator stack is shown in Fig. 3. The framework, somewhat resembling a cooling tower in shape, is of steel work with sides and partitions of concrete reinforced with expanded metal. The air passes through the openings in the roof at either side, and turns inward to the central chimney, which is open at the top and has no cover to deflect the sound. This chimney is divided into a number of cells, which prevent rain drifting at an angle from dropping through the openings into the engine room, and the under edges of the partitions are drained by gutters in the manner shown in the drawing. The partitions also assist in the breaking up of the sound. Fig. 2 (which does not represent a flying machine, as has been suggested) is a view taken during construction, and gives a good idea of the arrangement. The incoming air is drawn through a set of ducts under the engine-room floor from a special area covered with wire gauze. All the windows are double for the purpose of keeping the

Digitized by Google

sound in, and duplicate roller shutters, both lined with felt, are provided at all the doorways. The whole construction of the building, floor, walls, and roof is quite exceptionally massive, mainly, we believe, owing to the requirements of the London County Council under the Building Acts.

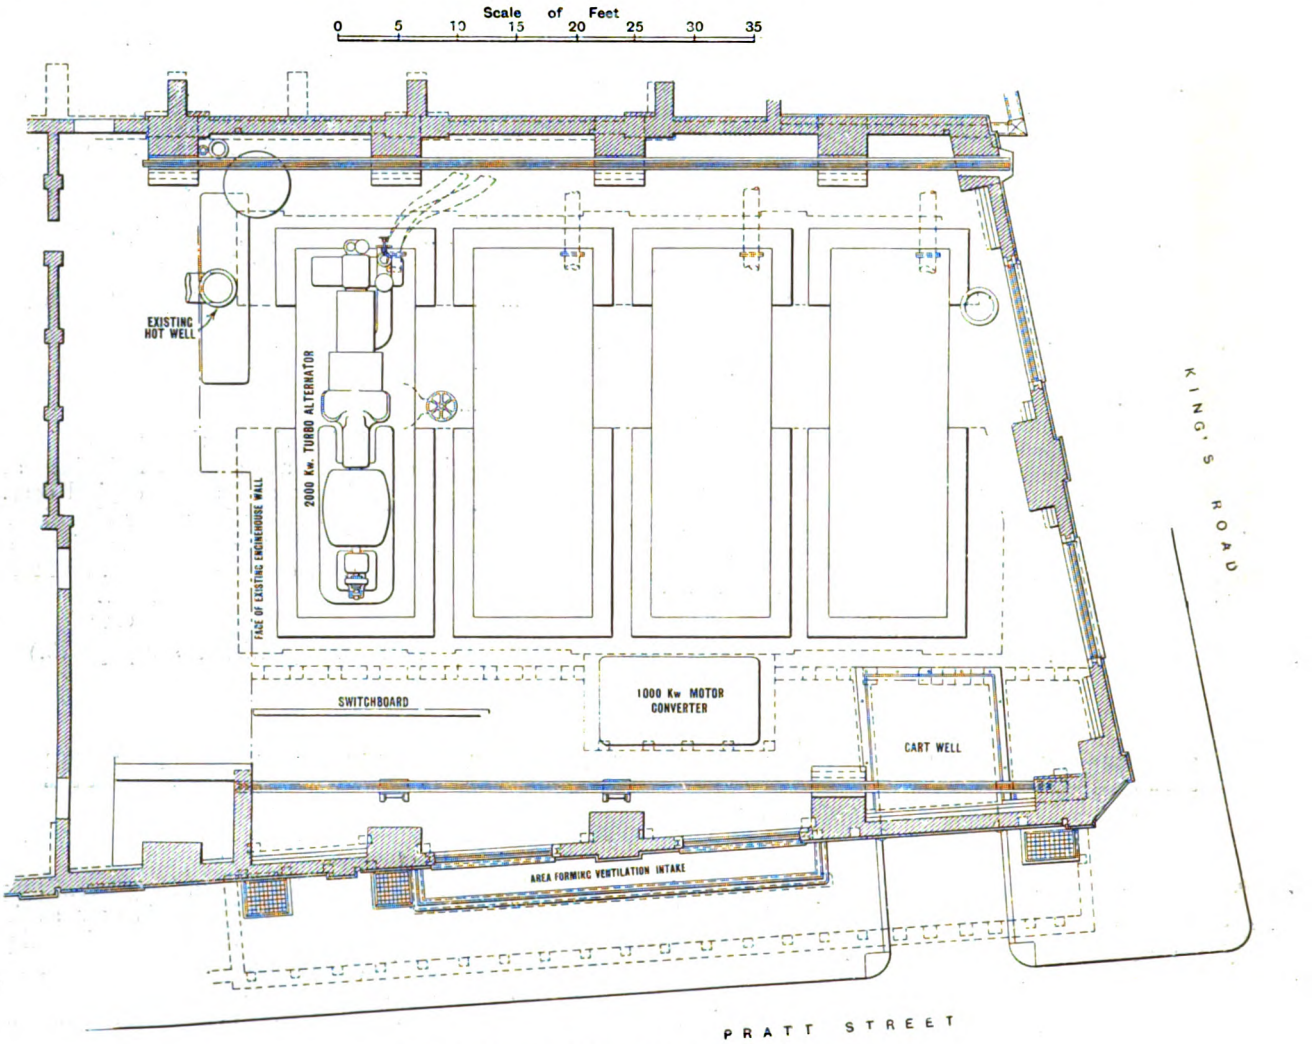

FIG. 1.—PLAN OF EXTENSION TO ENGINE ROOM.

The equipment at present installed consists of the 2,000-kw. Willans-Dick Kerr turbo-alternator, already mentioned, with its condensing plant, &c., and a 1,000-kw. Bruce Peebles-La Cour motor converter, together with the necessary switchgear.

The turbo-alternator consists of a standard Willans-Parsons steam turbine running at 1,500 r.p.m., supplied by Messrs. Willans & Robinson, of Rugby, and driving a standard four-pole three-phase alternator by Messrs. Dick, Kerr & Co., of Preston, a combination similar to a number of sets which have been installed in various generating stations during the last few years, an example of which, of similar size and construction, was described and illustrated in some detail in ELECTRICAL ENGINEERING, Vol. I., page 959. It will be remembered that the leading features of the Willans form of the Parsons turbine lie in the substantial nature of the blading, the design of the governor gear, and the extreme ease with which the whole turbine can be opened up for inspection. The turbine has its own condensing plant, also supplied by Messrs. Willans & Robinson, mounted directly underneath in the usual way, and, in accordance with this firm's practice, a rigid joint is used between the exhaust flange and the condenser body, while expansion is allowed for by mounting the whole condenser on springs. The air pump, of the Edwards type, is electrically driven, as is also the centrifugal circulating pump, which latter was manufactured by Messrs. W. H. Allen, Son & Co., of Bedford. Both motors are of Messrs. Bruce Peebles & Co.'s continuous-current type, running, like all the other auxiliary motors in the station, off the 440-volt mains. As circulating water is obtained from and discharged into the canal adjoining the station, no cooling towers are required.

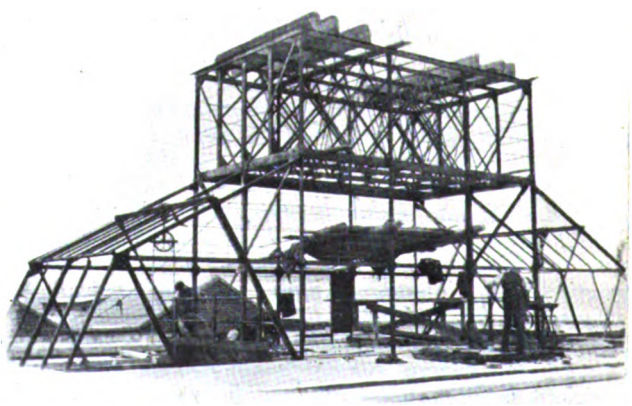

FIG. 2.—FRAMEWORK OF VENTILATOR UNDER CONSTRUCTION.

The alternator is of a type as well known as the

Digitized by Google

turbine, and embodies the usual features present in Messrs. Dick, Kerr's high-speed designs of salient poles, exceptionally rigid support of field windings and ventilation through apertures in the casing without the use of separate fans. Its rated normal output is 2,000 kw. at 5,000 to 5,300 volts, three-phase, 50 cycles, with an overload capacity at a power factor of 0·9 of 40 per cent. for four hours. The machine is star wound, and the neutral point is effectively earthed both to a large buried earth plate and to the pipe work leading to the canal. A 110-volt direct-coupled exciter is provided, but provision is also made for exciting from the 220-volt bus bars by means of resistances.

is provided all round, from which the rubber blocks can be inspected. Each rubber piece is a cylinder about 4¼ in. in diameter, and 3 in. in height, when compressed by the weight. They are all separately renewable, and can be withdrawn and reinserted without difficulty by compressing them further by tightening up the "jacks," in which they are held by screws. This, however, in other installations with this class of foundation has rarely been found necessary.

The new engine room is spanned by a fine 25-ton three-motor traveller, by Messrs. Adamson & Ramsbottom, of Birkenhead. The contract for the extensions we are considering did not include boiler plant,

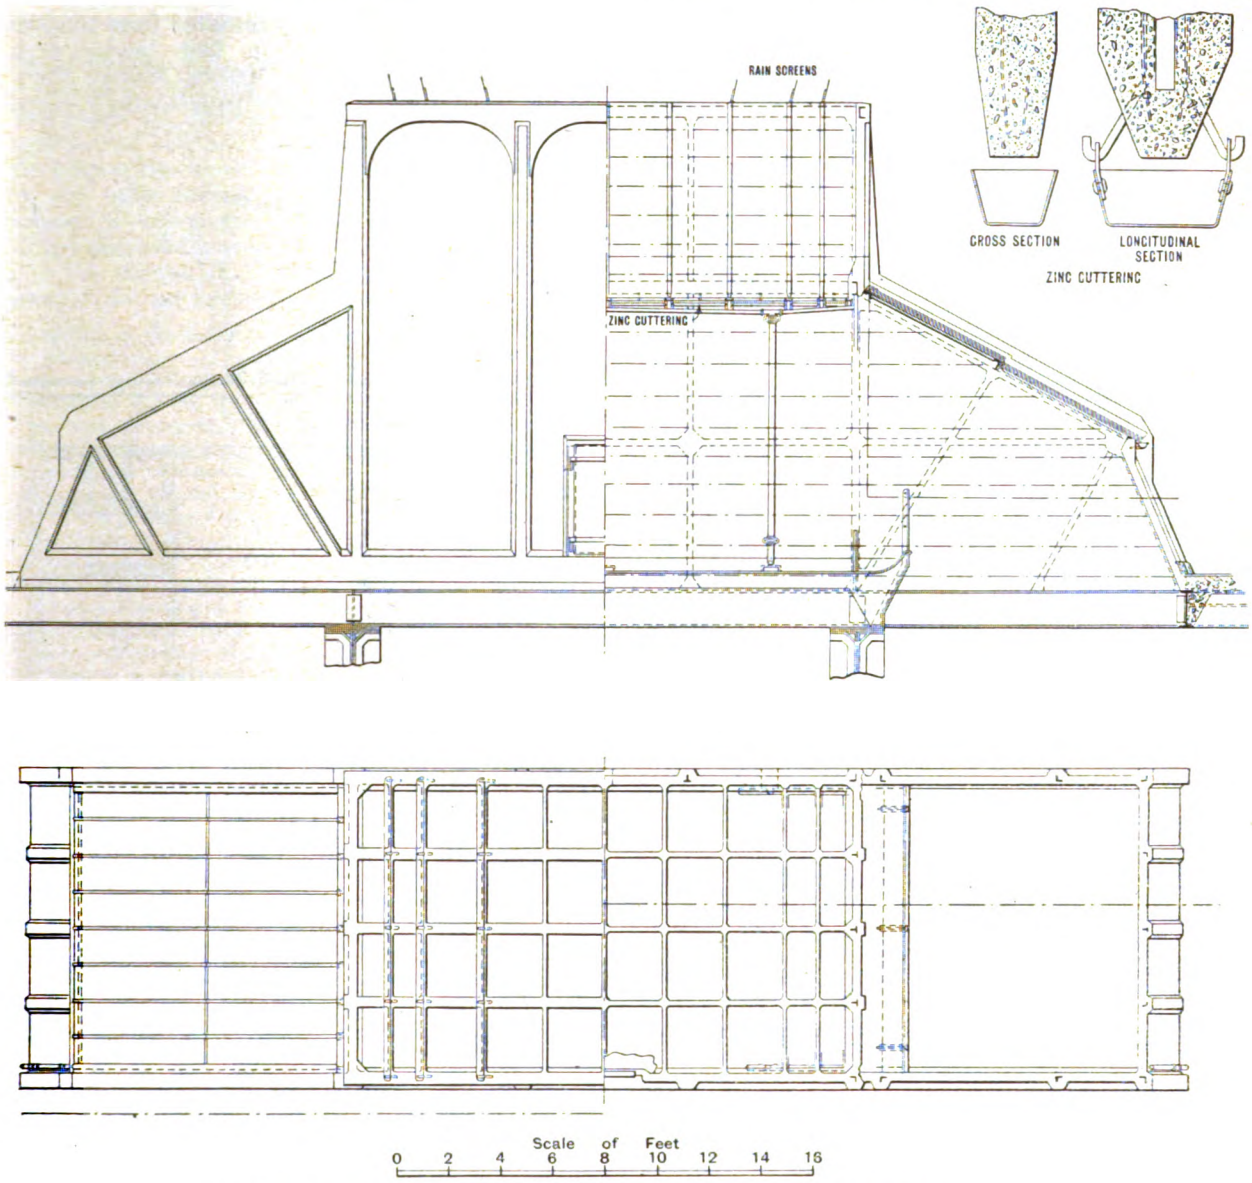

FIG. 3.—PLAN AND SECTION OF VENTILATOR IN ROOF OF ENGINE ROOM.

One of the most interesting features of the set is the arrangement of the foundations with rubber stools, according to the Prache system for avoiding transmission of vibration. The set is the first Willans turbine to be mounted on this form of foundation, and we believe the largest turbine of any kind to be so arranged. The set itself is bolted to a block of concrete about 2 ft. thick, reinforced with a steel grid, and supported entirely by a series of circular rubber stools near its edges all round, which rest on the ordinary concrete foundation built into the ground. The top of the floating block is level with the engine-room floor, but the edges stand clear all round, so that there is no connection except through the rubber. A trench

but a new boiler-house, with the necessary coal conveying plant, will ultimately be equipped. In the meantime provision for thermal storage is to be added to the existing boiler-house.

As will be seen below, the turbo-alternator can be connected by the switchgear which has been provided with it to the high-tension bus bars in the older part of the station for feeding the two alternating-current sub-stations which work in connection with the King's Road station, and for dealing with the additional load a new 500-kw. Bruce Peebles-La Cour motor converter has been installed in each sub-station for converting to 440 volts continuous current. It is interesting to note that these sets are also mounted on Prache anti-vibra-

Digitized by Google

tion foundations. For assisting, however, in the supply to those 440-volt continuous-current feeders which leave the King's Road station direct, the 1,000-kw. converter already alluded to has been installed in the new engine room, thus taking up the other half of the load of the alternator. This set is also of the Peebles-La Cour pattern supplied by Messrs. Bruce Peebles. It runs at 375 r.p.m., and, like the alternator, has an overload capacity of 40 per cent. for four hours. A particular advantage of this type of set for the purpose is the ease with which its action is reversible, enabling it to be used if required to allow the continuous-current plant to feed the alternating-current stations.

The position of the new switchgear is only indicated diagrammatically in Fig. 1. A number of concrete cells—high-tension switch cells—have been constructed on the engine-room floor level, and a gallery is under construction for the reception of the control boards. instrument transformers, &c., and the necessary isolating switches, are to be found within the cells. The generator oil switch release is equipped with a reverse current time limit relay, but no overload attachment is provided. The converter oil switch, on the other hand, in view of the reversible nature of this machine, is only furnished with a maximum relay set to operate at 100 per cent. overload. The converters at the sub-stations are, however, protected by reverse current relays, and a special feature of the arrangement is the way in which the cell doors are interlocked with the isolating switches, so that the interior of the cells can only be accessible when the isolating switches are open.

The exciter switchgear is actuated from the generator desk panel, and includes a large series regulating rheostat manufactured by Messrs. Ernest Moy, Ltd., of Camden Town. The new panels simply connect up

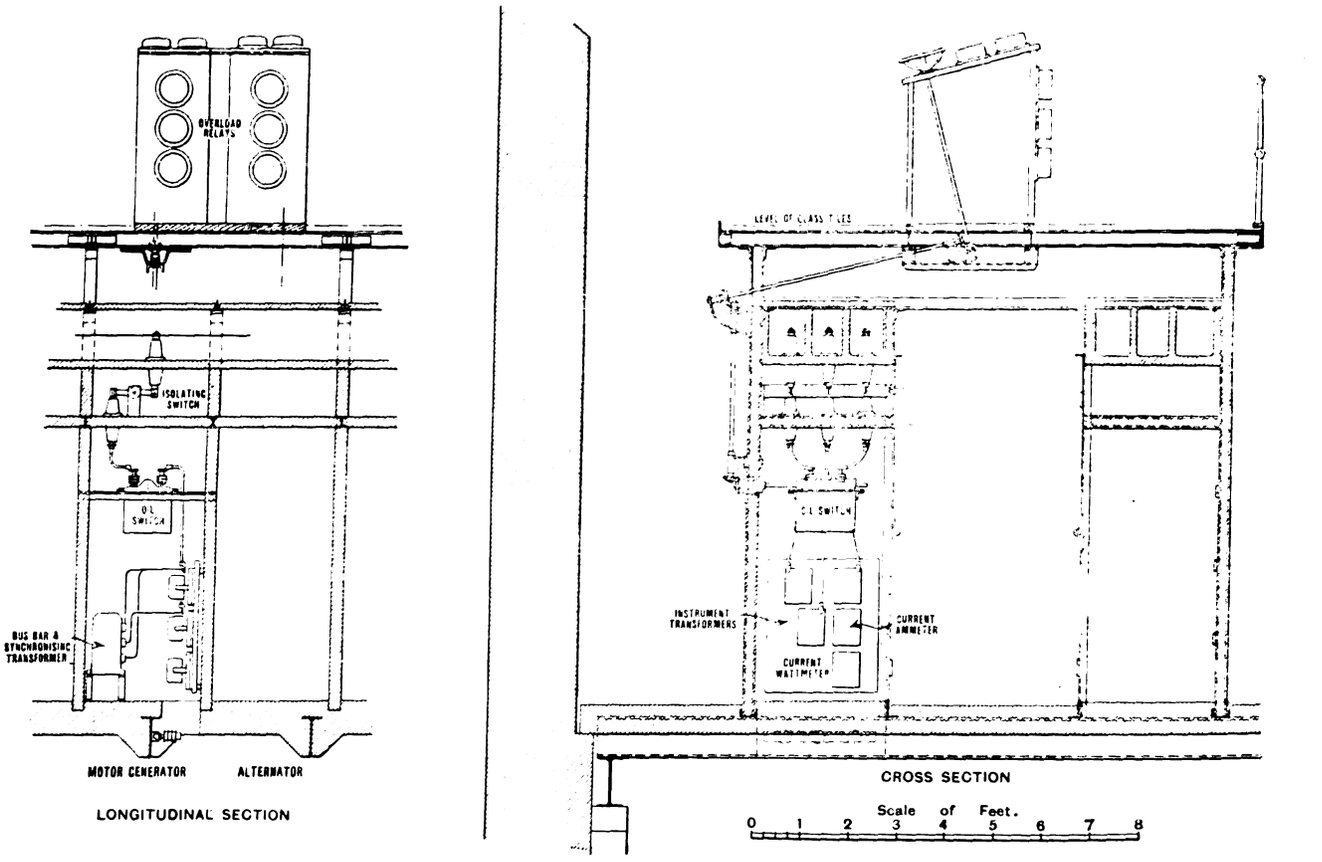

FIG. 4.—SECTIONS SHOWING ARRANGEMENT OF H.T. SWITCH CELLS AND DESK TYPE CONTROL BOARD.

Up to the present only two of these cells have been fitted up, but it is intended ultimately to transfer some of the high-tension switchgear from the older part of the station to these cells in order to have all the gear of this nature together. The two cells already equipped have their "desk" pattern control gear mounted immediately above them, and serve as generator and motor converter panels respectively. The cells are constructed in steel frames, with sides of reinforced concrete, and the whole arrangement is of a special design. The generator panel was equipped by Messrs. Dick, Kerr & Co., with their own make of high-tension switchgear, but switches manufactured by the A.E.G. Co. are employed in the converter panel. The arrangement of this latter panel is shown in Fig. 4. In both cases the main oil switches are hand operated by mechanical connections from the desk board above, but the details are slightly different; for example, a lever is employed in one case, and a handwheel in the other. A full equipment of to what may be regarded as an extension of the main high-tension bus bars of the old A.E.G. board, to which the feeder cables are brought up, and where the necessary protective spark gaps, &c., are provided. The starting gear for the motor converter is situated on the floor close alongside the set itself. Connections from the continuous-current side of this set, in the form of two bare copper strips each 4 in. by $\frac{1}{2}$ in., separated by an air space and supported on porcelain insulators, are taken along the wall to the main continuous-current board in the older part of the station.

The whole of the extension is interesting as an example of really up-to-date central station practice, embodying some novel features, and we must express our thanks to Mr. Sydney W. Baynes, Chief Electrical Engineer to the Borough of St. Pancras, who is responsible for the design of the buildings and plant, for the loan of drawings, for personally conducting our representative over the station and extensions, and for giving us full information.

"THE ELECTRICAL LEAGUE"

THE following gentlemen have formed themselves into a Provisional Committee, for the formation of an "Electrical League."

G. L. Addenbrooke, A. K. Baylor, Lt.-Col. H. R. Beddoes, E. Bergtheil, A. N. Connett, Bernard M. Drake, W. B. Esson, E. H. Freeman, E. Garcke, G. Marsden Gibson, F. E. Gripper, H. Hirst, M. B. Mountain, W. M. Murphy, H. B. Renwick, Mark Robinson, G. Sutton, A. A. Campbell Swinton, and R. Borlase Matthews, Hon. Sec., 1 Victoria Street, Westminster, S.W.

They are issuing a pamphlet inviting all people who are connected in any way with the industry to join it, with the object of making a united effort to improve the condition of the electrical industry by impressing its claims upon the Government and other authorities, and by any other means in their power. No definite programme of action has been formulated, and the aims of the proposed league are set forth only in general terms in the pamphlet. The following summary has been sent us for publication:—

The condition of the electrical industry, as a whole, is in many respects unsatisfactory. The cause is very largely premature and ill-advised legislation. The apathy of the Legislature is the chief obstacle to reform, as electrical interests in this country possess no suitable organisation through which they can make their collective influence felt, and members of Parliament have no sufficient means of hearing our side of the case; consequently electrical questions are not always decided on their merits, but according to the pressure which is brought to bear.

The Institution of Electrical Engineers has in the past made some efforts to secure attention, but is not able to carry on political propaganda. Any differences between various sections of the industry should not, however, be a bar to united action in matters of common interests. The Electrical League is being formed as a combination of individuals; and the invitation to join the League is extended to everyone who is in any way interested in electricity, whether as shareholder, consulting engineer, town councillor, manufacturer, contractor, or trader—whether employer or employé. The subscription is 2s. 6d. per annum, which may be commuted by a single payment of £1.

Whatever the opinions or the interests of the individual members may be, the League in its collective capacity will start with neutrality on contentious matters, and no action will be taken on any question of policy, except in accordance with rules to be approved by members. The ultimate objects of the League will be to endeavour to reconcile conflicting views, and to assist the development of the industry in any manner found advisable after careful consideration of the causes which hamper business and diminish prosperity.

Every endeavour will be made to work in co-operation with established electrical societies.

The details of the organisation are to be formulated by a council to be elected by the members.

The need for the organisation is urgent.

In the pamphlet itself it is stated that nearly £300,000,000 is invested in registered electrical companies in this country, and £80,000,000 more in municipal electrical undertakings, that the profit earned on this is declining, and the market value of shares in electrical companies has depreciated heavily. The complaint is made that while our electrical industry is suffering under adverse legislative conditions, electrical manufacturers and contractors in foreign countries have, with the assistance of their Governments, been able to strengthen their positions so as to take advantage of our difficulties. It is argued that the reason why the Legislature in this country does not deal sympathetically with the situation is mainly that those who are interested in the industry fail to secure Parliamentary attention, they lack cohesion, and are unable to make themselves heard. The founders of the "Electrical League" propose to create an organisation through which the diverse electrical interests in this country can make their collective influence felt. Referring to the Institution of Electrical Engineers, the pamphlet says that on the professional and scientific side the Institution is a thoroughly representative body, "but it does not profess to deal actively with the commercial, financial, and political aspects of electrical enterprise." The other societies representing various branches of the industry, it is added, speak only on behalf of their respective sections, and they fulfil their specific purposes best when confining themselves to these sections. Facilities are required, however, for the elimination or adjustment of sectional differences and for joint action.

Emphasis is laid on "the force and weight of numbers" that the proposed "Electrical League" would possess, as all are invited to join it who are in any way connected with the industry, and the subscription is fixed at an almost nominal figure. It is to be a combination of individuals rather than of Corporations or firms, and as the computation has been made that there are 300,000 persons dependent on the electrical industry for their means of livelihood, and in addition 125,000 investors in electrical companies, the organisers of the League feel that mutual jealousies due to conflicting interests within the industry will be overcome, and that by its means joint action on important matters can be taken by a body which would be thoroughly representative.

The pamphlet concludes as follows:—"In view of the probability that fiscal, social, and industrial questions will occupy a prominent place in the practical politics of the near future, it is eminently desirable that the electrical industry should be represented by an organisation able to enforce a consideration of its claims. For this reason alone it is of the greatest importance that the various sections should be brought together, as has already been done in the case of other important industries, so that they may be agreed upon the course to be pursued when the opportunity for action arises."

The Metal Filament Lamp in America.—An interesting article by Dr. Louis Bell, in last week's *Times Engineering Supplement*, deals with the position of the metal filament lamp in the United States. The supply pressure in that country is usually 110 volts, and in consequence the 25-volt lamp supplied through a transformer or auto-transformer has made little progress. Accustomed as they are to 16-c.p. lamps, the natural thing for the American consumer to do is for him to employ in their stead the 20-c.p. metal filament lamp, which, Dr. Bell says, the "ruthless Teuton" is pushing actively in America, with the result that American manufacturers are producing a 25-watt 20-c.p. lamp to compete with the 25 Hefner candle-power unit of the Germans. There has been a considerable sale of German lamps, but at the prices now current the American lamps are slightly cheaper, and the imported lamps, Dr. Bell says, while at present finding a ready market, are not likely to be a permanent factor in the situation. A few stations are trying the experiment of free renewals of metallic filament lamps, the effect of which cannot as yet be foreseen. In the writer's judgment it is bad policy, so long as present prices are maintained, by reason of the risk of untimely breakage. The man who buys a lamp for three or four shillings will try to use it gently, while if he gets it free the care it receives is not a matter that directly concerns him. Under such conditions the station that undertakes free renewals is in effect cutting its price to an extent that seems hardly warranted by any probable increase of demand. Dr. Bell thinks that the situation generally will not cause the least uneasiness to the central station men, and he adds that a valuable characteristic of the lamp is the ease with which it lends itself to series street lighting, which is still a striking feature of American practice. For this service excellent tungsten lamps are available, in sizes from 25 c.p. upwards, and with relatively short and stout filaments. On the whole, he concludes, American experience with metal filament lamps is most encouraging. They have so far done much good and no harm, "unless one objects to the frequent replacement of the American enclosed arc lamp, the oblivion of which is, on its merits, already overdue."

THE BOURNEMOUTH CORPORATION TRAMWAY SYSTEM

AS the result of the somewhat severe comments of Major Pringle, one of the inspecting officers of the Board of Trade, upon the tramway department of the Bournemouth Corporation, in his report upon the accident on that system on May 1st, it will be remembered that the Corporation called on Mr. J. B. Hamilton, general manager of the Leeds Corporation Tramways, to advise upon the administration and working of the system in Bournemouth. Major Pringle complained that there was not a regular tramway manager at Bournemouth, and that no one officer was responsible to the Corporation for the administration of the whole undertaking. He strongly advised that a change should be made in the organisation by the selection, in open competition, of a properly qualified general manager, who should have control of the whole department. In reply to these criticisms, reports were furnished by the Borough Electrical Engineer and the Engineer and Traffic Manager, setting forth the duties of the various officials, and claiming that the present system was efficient. (ELECTRICAL ENGINEERING, Vol. IV., p. 469). In our last issue we briefly referred to Mr. Hamilton's report, and by the courtesy of the Town Cerk are now able to give its contents at considerable length. Generally, it may be said that Mr. Hamilton's report is in agreement with the remarks of Major Pringle.

In his preliminary remarks Mr. Hamilton says that the scheme generally, apart from the novelty of combining conduit with overhead traction, has been developed upon lines which are familiar all over the country. The whole circumstances of operation, width of streets, curves and gradients of routes, and distribution of population, point, with careful management, to more than average safety in working and satisfactory financial results. The complete equipment of the undertaking, he says, is in good average working order; the power station well maintained; the rolling stock, as befits a town of the attractive reputation of Bournemouth, more than usually elegant externally, whilst internally it is sumptuously upholstered; and the permanent way, although showing signs of wear and corrugation in several places, of substantial construction. Before dealing with the various sections of the undertaking seriatim, Mr. Hamilton states that as a result of a full consideration of all the factors in the case, he is of the opinion that the immediate causes of the accident on May 1st, which resulted in the death of seven passengers and injury to 26 others, were as follows :—

1. The injudicious and extreme use of the hand-wheel brake by the motorman as the car entered the Fairlight curve.

2. The absence of any super-elevation on the outer rail, which was considerably worn at the tangential or curving point. The high speed which had been attained, combined with the frequent and quick reversals of curvature, set up a large amount of swaying of the car, whilst the application of the hand-wheel brake held the wheels quite rigid. When the car, therefore, struck the curving point it lurched outwards owing to the absence of super-elevation. The inside wheels were thus swung clear of the inner guard rail, and as the outer rail was much worn there was nothing left to guide the car round the curve, and it consequently proceeded in a direct line.

Rolling Stock.—It will be remembered that Major Pringle reported that the initial cause of the car on May 1st getting out of control was the incorrect position of the reversing barrel of No. 1 controller at the rear end, which rendered useless all the electrical braking equipment whilst the car was being driven from No. 2 controller. Consequently, Mr. Hamilton centred his chief interest in the condition of the controllers. In this connection the report states :—The type of controller on 70 out of the 81 cars is that supplied by the Westinghouse Co., types 90 and 90M. In these types the reversing barrel is mechanically rotated automatically when the power handle leaves the power notches for the "off" or brake position. In the movement from power to "off," half the full motion takes place towards reversal, but from power to brake the full motion of the reversing barrel takes place, and hence the complete changing of the armature leads. This is, as before stated, accomplished mechanically. On the top end of the main power barrel shaft are keyed certain cams. These cams, through suitable levers and rollers, and a rack and pinion, communicate motion to the reversing barrel. With an arrangement of this description it is obvious that the outside operating lever, called the reverse, cannot be keyed permanently to the reversing barrel. Its function must be to determine whether the first movement of the power handle from, say, "off" to "power," shall, through the media of cam racks, &c., move the reverse barrel from right to left or *vice versâ*. This is accomplished by the use of a double rack, *i.e.*, two racks in the form of a jaw with pinion keyed to the reverse barrel between them. The width of the jaw and the pitch of the teeth are so arranged that either rack can be in engagement with the pinion. Evidently, then, the longitudinal movement of the jaw with one of the racks in engagement will cause rotation of the reverse barrel, and the direction of rotation will depend on which rack happens to be in engagement. This is determined by the position of the reversing lever on the outside of the controller.

The above arrangement is certainly very ingenious, and possesses some advantages over the simpler forms of controllers. It does away with the necessity of an additional barrel on the main power shaft, and hence economises space, or, what is perhaps better, leaves more available space for contact rings and fingers. On the other hand, it has a serious and dangerous disadvantage. It is possible under some circumstances for one of the racks when coming into engagement with the pinion to slip and engage with the wrong teeth. This has the unfortunate effect of altering the relative position of the reversing and the main barrels, with the result that the reversing handle may be removed in the same way as if the barrel were at the "off" position. Further, this can happen unknown to the driver, who first finds it out when he endeavours to use the electric brake from the other controller, which he finds, as a result of the defect in the first controller, is out of action.

To overcome the above described defects, a new form of interconnecting gear between the main and reversing barrels has been devised, where the rack and pinion is dispensed with. With this scheme the reverse handle when put home to the "forward" or "reverse" position moves the reverse barrel on to the proper forward or rear contacts, and so long as use is not made of the brake notches no movements take place in the inter-connecting gear or of the reverse barrel. This, of course, has the effect of materially reducing wear in the moving parts. When the brake notches come into use, *i.e.*, when the main barrel passes from the "off" to the first brake contact, the reverse barrel is rotated over from the contacts representing the direction of car movement to the opposite set in an exactly similar manner to the rack and pinion scheme.

The rack and pinion is, however, replaced by a disc having two slots cut in a radial direction from the centre to the circumference at a certain angle to each other. In the slots are vertical sliding pins, forming the ends of the cam-actuated levers from the main barrel. The position of these pins in the slots is determined by the position of the reversing handle, and hence the direction of rotation of the reversing barrel relative to the main power barrel. As this scheme does not in any case change the permanent mechanical connection between the two controller barrels, it is evident that the relative position of the two barrels must remain the same under all circumstances insomuch as they are permanently interlocked as positively as the piston and crank shaft of a steam engine. In most of the other types of controllers, which are common throughout the country, this defect cannot occur. In the 11 cars which the Corporation took over from Poole, the controller fitted is the B.T.-H. B 3 type. In this controller it is immaterial whether the reversing barrel is put at the "off" or "on" position, as this does not affect the controller at the other end of the car in any way. In the Dick-Kerr examples, again, if the reverse barrel is left in the "on" position it is impossible to move the car from the other end.

The point which I wish to make, continues Mr. Hamilton, is that these controllers are more dangerous than those generally in use, as they may be out of order, and the fact never discovered until the moment of emergency occurs. The invention to which I have referred, as simplifying the mechanism operating the forward and reverse barrels, would, I believe, make it absolutely impossible for the reversing barrel to be in contact with the main barrel whilst this lever was at the "off" position. I have arranged for one of your controllers to be so altered and put into service. If found satisfactory, I suggest that the whole of the controllers of this type should be altered in this way, and so remove the possibility of their getting improperly into contact. As a precaution, I note that Major Pringle has recommended that all controllers at every terminus before the handles are removed should be opened and the barrels examined for their proper "off" position. This, I take it, is a tentative precaution. In darkness it is quite possible for a barrel not to be "off" without this being noticed by the motorman, whilst the opening of the controllers by allowing rain or moisture to get in is certain to cause other troubles.

I feel sure if the Corporation adopted the arrangement I have suggested, that the necessity for opening the controllers would be entirely removed, and, therefore, the Board of Trade regulation would be withdrawn. I am pleased to say that, on making a complete examination of the controllers, I found them generally in very good order. They certainly showed evidence of many new parts having been lately supplied, whilst the racks had also been tightened up. The motors and other parts of the

Digitized by Google

equipment, including magnetic brakes, also seemed to be in a state of high efficiency.

Mr. Hamilton disagrees with the policy hitherto adopted of allowing cars to return to a different depôt to that from which they started, and recommends that the usual practice be followed of allotting cars to each depôt and foreman, and holding him responsible under the rolling stock superintendent for the general condition of these cars. He does not find fault with the number of men employed at the outside car depôts, nor with their wages.

Central Car Depôt.—There are 103 men engaged here in the repair, maintenance, and cleaning of 61 vehicles, the average number in use for each 19-hour day, of which 21 are described as cleaners, and no exception is taken to the latter number. It is recommended, however, that the number of fitters, turners, machinists, brakesmen, controller and truck men should be reduced by five or six, and reductions are also recommended in the number of car-body makers and painters. The general lay out of the works in the central depôt is found fault with, the track and pits laid off for doing the principal overhauling and repairs being too far away from the machines and shops. Several suggestions are made in this connection.

Sanding Arrangements.—In order to make these more satisfactory, and to avoid the use of a curved tube or other appliance, it is recommended that the sand pipe should be brought back about 4 in. and placed inside the pilot board.

Stores.—The report does not consider that the stores are kept in a really systematic and orderly manner, as although the storekeeper and his assistants knew where the things were, the labelling of the different bins had not been carried out thoroughly. The accommodation is also considered inadequate. Under this head reference is made to the fact that on the date of the accident about 20 cars were in operation with only three magnets instead of four, due to there being no spare ones in the stores. Whilst agreeing with the views of the Engineer that there is very little difference in the retarding effect of three magnets as against four, Mr. Hamilton recommends that there should, in future, be a standing instruction that no car should be allowed on service which is not fully and properly equipped.

Maintenance and Repair of Overhead Equipment.—Satisfaction is expressed with the arrangements in this connection.

Power Station.—The output for last year for all purposes was nearly 2,000,000 units at a cost of 1·626d. per unit. Mr. Hamilton selects Huddersfield as a comparable undertaking, where the costs, including sinking fund and interest, &c., is 0·65d. per unit, and thinks that the costs should certainly be considerably lower, even after taking account of the higher fuel costs, which are inevitable in Bournemouth.

Permanent Way.—There are a good number of places where the foundations have given way with the result that the line is wavy. This sets up a swaying motion of the cars, which strains the rolling stock very considerably. At the spot where the accident took place increased super-elevation is recommended, as well as at some other curves, after consultation with Mr. C. A. King, Consulting Engineer to the Metropolitan District Railway Co., whose report on this question is embodied in that of Mr. Hamilton. It is estimated that the cost of this will be about £1,000.

General Office Work.—The book-keeping is on most up-to-date lines, and no adverse comments are made.

General Traffic Arrangements.—It is recommended that the method of training drivers should be better organised. At present this is carried out in a somewhat perfunctory manner by allowing conductors to accompany drivers during their spare time, but they receive no training in the depôt as to the general working of the different parts of a car, nor are they periodically tested to see if they understand how to cut out motors, or for other emergency conditions. It is not thought necessary to provide a school for drivers, and suggestions are made for obviating this expenditure. The staff for the working of the traffic is regarded as too large, and the opinion is expressed that Mr. Barber, the Manager, has in the past handicapped himself by an anxiety to supervise many details which ought to be relegated to an assistant.

Organisation.—It is thought that there are too many officials in charge of different sections of the undertaking, without a responsible head. The present salaries, including five chief officers, now amount to £1,475, but Mr. Hamilton thinks the following would be sufficient for the working of the department :—General Manager, £600 per annum; Electrical Engineer, £200; Rolling Stock Superintendent, £175; Traffic Superintendent, £175. This would result in a saving of £325 per annum.

Fares and Stages.—The average of the 1d. stage works out at 1·19 miles, which is below the average of the larger provincial undertakings. Taking into account, however, the conduit system and the expensively upholstered cars in Bournemouth, which are not found in the provinces, it is not recommended that there should be an increase in the length of the penny stage.

Services.—The average speed, including all terminal and service stops, is 6·67 miles per hour compared with 7·3 miles in eleven of the principal provincial towns where the gradients are much more severe, and is unduly low. If an average speed of 7·17 miles per hour could be arranged for, a saving of over £1,300 per annum would be made, whilst increasing the attractiveness of the service.

Financial Position.—Mr. Hamilton has considered all the items of revenue expenditure for the year 1907–8, and thinks that reductions are possible in "clearing, salting and sanding track," "ticket check," "general expenses," "repairs and maintenance of buildings and fixtures," "workshop, tools, and sundry plant," and "cars." "Power expenses" are also considered excessive, although the fixed prices of the power purchased in Poole and Christchurch will always maintain high costs per car mile. Another item which must militate against low costs are the heavy sums for sinking fund and interest, it being an obligation to set aside 4½d. per car mile for these items owing to the heavy capital expenditure on the installation. In this connection, the running of a Sunday service is strongly recommended as a source of large profit, estimated at from £4,000 to £5,000 per annum. If the proposed scheme of re-organisation is adopted, it is estimated that there will be a saving of about £4,000 per annum.

General Financial Position.—There is at present the sum of £25,446 accrued from unappropriated surpluses. Mr. Hamilton, however, advocates depreciation at the rate of five per cent. per annum, and on this basis the amount available should have been not less than £35,000. From this it is argued that apart from any claims which may arise as a consequence of the accident on May 1st, there is a deficiency in renewals fund of £8,000 to £10,000. During 1904–5 the fund, which had increased to £9,633, received an addition of £7,918. In 1905–6 this was augmented by £6,416 to a total of £23,968. In 1906–7 an addition of only £1,061 was made, whilst in 1907–8 a reduction of £610 occurred. These figures, concludes the report, speak eloquently for themselves, and indicate that the time has come when the Corporation should seriously consider the situation, and adopt strong measures with regard to their future policy in the working of the Tramways Department.

Northampton Institute.—The London County Council has made a grant of £5,600, asked for by the Governors to complete the equipment of the electric generating station at the Northampton Institute. We gave full particulars of the matter on page 809 of our issue for December 24th.

The Brennan Monorail.—The *Australian Mining Standard* states that some time ago Mr. Louis Brennan made an offer of his monorail to the Australian Commonwealth, and the late Government was considering the proposal at the time of its going out of office. The terms of the offer were that in consideration of the Commonwealth providing £11,500 for the construction of the first full-sized car, and to enable the inventor to perfect his invention, the Commonwealth Government shall have the sole right for Australia to manufacture other cars on payment of a royalty of 5 per cent. on the cost price of all cars built within ten years after delivery of the first car ordered by the Commonwealth. Further details are being asked for.

Wireless Telegraphy.—The French warships at Messina are, according to the *Daily Telegraph*, in communication with the Eiffel Tower and the Sainte Marie (Marseilles) wireless stations. The Italian stations are also in touch with the ships at Messina, which are provided with wireless apparatus, so that although the cables connecting Sicily and the mainland were broken by the earthquake, communication with the island is not cut off.

With regard to the arrangements between the Meteorological Department and the shipping companies owning ships on the Atlantic routes, we understand from the *Daily Chronicle* that the first weather reports under these arrangements were received through the Marconi Company's Clifden station on the west coast of Ireland on Sunday last. It is expected that five or six reports from various parts of the Atlantic will reach London daily when the scheme is in full working order.

Electric Locomotives on the District Railway.—Since the running of the London & North-Western trains over the District Railway from Earl's Court to Mansion House has been discontinued, the electric locomotives which were formerly used for hauling these trains between the above-named stations have been used for the ordinary service of the railway. The arrangement forms an interesting example of the flexibility of multiple-unit operation. The locomotives, as used for hauling the London & North-Western trains, consisted each of two double-truck units, each provided with two 200-h.p. motors, with a full multiple-unit equipment on each of the two cars and master controllers at each end. In the present arrangement one of these cars is used at the head of the train, and works in the usual way in conjunction with one or more motor-cars in other parts of the train. The control equipment only differs from that of the ordinary motor-cars in that the resistances, contactors, and other gear are entirely within the all-steel bodies of the locomotives instead of under the frames. Although the London & North-Western trucks were fitted with vacuum brakes, and the District trains with the Westinghouse compressed-air brake, very little alteration has been required, as a form of vacuum pump was used which could be converted to a compressor supply by interchanging the pipe connections.

CO-OPERATION IN ELECTRIC POWER SUPPLY

IN a Paper read on Monday last before the Cleveland Institution of Engineers, Middlesbrough, Mr. A. B. Gridley, of the Cleveland & Durham Electric Power Co., dealt with the application of electricity to the reduction of the waste of energy, capital, labour, &c., and particularly with the utilisation of waste heat on the co-operative principle. The problem, said the author, was a very wide one, and it was necessary to explain that the considerations in the Paper were based upon the conditions existing in the immediate district, where electricity was available from public sources at reasonable prices.

Dealing first with the advantages of electric driving, the author pointed out that electric motors have an absolutely uniform turning moment which must result in less strain being put upon the driven machines, and consequently enable them to

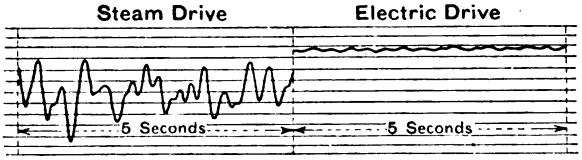

FIG. 1.—COMPARATIVE TACHOGRAPH RECORDS FOR STEAM AND ELECTRICALLY-DRIVEN MILLS.

be run at an increased speed. The difference is marked in the case of a gas engine, but even in the case of a high-grade steam engine the comparison is sufficiently striking. Fig. 1 shows actual tachograph curves from the drive of a textile mill, the first driven by a steam engine, and the second—the same mill—electrically driven. Mill-owners find that they can run their plant at 10 per cent. higher average speed, and, on account of fewer thread breakages, they can produce fabrics of finer texture with electric driving. The high rates of acceleration which can be obtained with electric motors enable greater rapidity of travel by electric trains and trams, and increased operating speeds for haulages and winders at coal and ironstone mines. This rapid acceleration is strikingly illustrated in Fig. 2, which shows speed-time curves of a steam and an electric train respectively. Although the steam train reaches a maximum speed of almost 45 miles per hour, while the electric train does not exceed 40, the latter on a short run on a suburban line has a higher average speed with a lower maximum speed. In the schemes of electrification of suburban railways, which have been considered, it has been possible to estimate for a 25 per cent. increase in the average speed.

On Tyneside, electricity has practically superseded steam, and large undertakings such as the North-Eastern Railway Co., Armstrong, Whitworth & Co. (ELECTRICAL ENGINEERING, Vol. I., page 155, and Vol. IV., page 91), Swan, Hunter & Wigham Richardson (ELECTRICAL ENGINEERING, Vol. IV., page 275), and practically every other power-using company have discarded

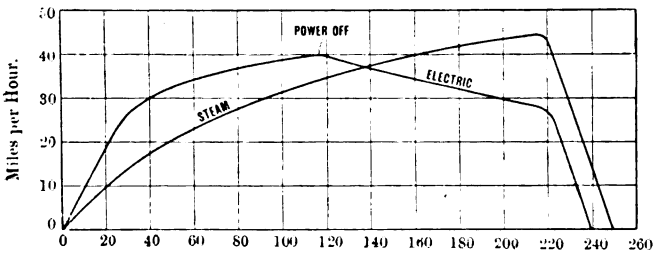

FIG. 2.—TYPICAL SPEED-TIME CURVES FOR STEAM AND ELECTRIC TRACTION.

private electrical generating plant, and both gas and steam direct-driven plant, and have become purchasers of electrical energy. On Teeside the same spirit of progress is being shown, and although progress has been less rapid, several private plants have already been superseded, and the ultimate abandonment of most, if not all, remaining isolated generating stations will only be a matter of time.

Where a variety of undertakings are being supplied, there is a wide diversity in the times at which they make their respective demands on the power station. Experience on the north-east coast definitely proves that works whose installations aggregate 120,000 kilowatts can be supplied by 40,000 kilowatts of plant run at the power stations. The demands of all these works, if made at the same moment, would probably amount to 70,000 to 90,000 kw., and if their own plants were installed, plus say 33⅓ per cent. for spares, about 106,000 kilowatts of plant would have to be purchased. The cost per kilowatt would probably be approximately £30, taking both large and small installations, and including land, buildings and plant, &c. The total capital expenditure on private plants would therefore reach £3,180,000. In the case of the supply authority, allowing again 33⅓ per cent. reserve plant, 53,000 kilowatts only would be required, and pricing the capital cost of these at £20 per kilowatt, due to the purchase of larger units, less land and much less building material, the total cost would be £1,060,000, or a saving of £2,120,000. There are still not yet electrically operated in the Tees district installations aggregating nearly 200,000 h.p., or, say, 150,000 kw. Working out the capital saving on the same basis, we get £4,770,000 saved in generating plant in the district. Out of this we have, of course, to allow for the cost of the transmission and distribution mains and plant, and if we assume that these cost nearly £2,000,000, there is a saving of something of the order of £2,750,000. It may be argued that when specific cases have to be considered, it may be that the expenditure of some of this capital is justified where lower operation costs can thereby be achieved. It will not, however, be easy to find many instances of this sort, and certainly few which cannot justifiably be brought into a co-operative scheme.

The savings possible by the concentration of electric power production in large central generating stations are of real importance in the matter of coal and water. In a Paper read by Mr. Charles H. Merz before the Iron and Steel Institute during their recent visit to Middlesbrough (*see* ELECTRICAL ENGINEERING, Vol. IV., pages 505 and 523), he pointed out that if all the colliery owners in this district purchased their power from an outside source, 1,750,000 tons of coal per annum, worth, say, £500,000, would be freed for sale. It is estimated that the coal consumption of Great Britain is about 170,000,000 tons per annum. Of this quantity 71,000,000 tons are used in factories and mines, 13,000,000 on the railway systems, and 28,000,000 tons in the iron and steel industries. Taking the consumption in factories and mines as 60,000,000 tons for power purposes only, it is calculated that, with electric driving, the consumption could be reduced by at least 50 per cent. Pricing the 30,000,000 tons saved per annum at 7s. 6d. per ton, this represents an annual saving of over £11,000,000. In addition to this the life of the British coalfield would be considerably prolonged.

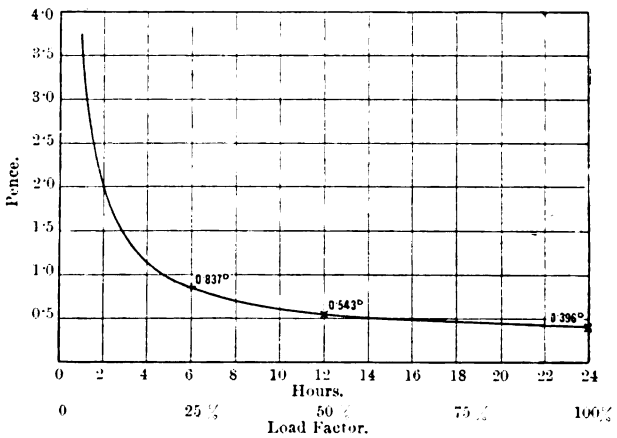

FIG. 3.—TARIFF CURVE SHOWING AVERAGE PRICES OBTAINED WITH DIFFERENT LOAD FACTORS ON A BASIS OF £4 PER H.P. PER ANNUM, PLUS 0·25D. PER UNIT.

There is being wasted, at the present moment, a large amount of energy in the form of exhaust steam, waste heat, and combustible gas. This is largely due to the fact that there has hitherto been no real market for surplus power, so that the owners of it have not found it commercially sound to spend the capital necessary in order to enable it to be utilised, and also because no works, where a large amount of waste heat is available, has a power load of sufficient magnitude or constancy to enable the continuous supply of energy which can be generated from waste heat to be anything like fully utilised. It therefore follows that either some of the gas or steam must be allowed to go to waste and a portion of the generating plant stand idle, or partially employed only, or an arrangement made with a wholesale power supplier for the disposal of the surplus current that can be generated. In other words, it is only by co-operation with a large power company that the ideal of getting as near 100 per cent. load factor as possible becomes feasible.

The author then showed, by means of a map of the distribution network of the power companies of the north-east coast

Digitized by Google

district (see ELECTRICAL ENGINEERING, Vol. IV., page 505), how this principle of co-operation had been acted upon in that district. The chief power stations supplying this network are Carville, Philadelphia, Neptune Bank, Blaydon, Hebburn, Grangetown, Newport, and Weardale; all these stations are in operation. Others under construction are Dunston, Bankfoot, and Tees Bridge. The waste heat stations at Blaydon, Weardale, Newport, Bankfoot, and Tees Bridge are or will be run at their full capacity day and night, the coal-fired stations being ready to deal with such load as these stations are unable to supply, and also with peak and other loads which may arise owing to the partial cessation of a waste heat station due to temporary interruption in supply of waste heat or gas, as the case may be. Although there is being supplied at the moment from the south to the north about twelve times the amount of current sold by the Middlesbrough Corporation, this is only about 5 per cent. of the current required by the Newcastle and Durham Power Companies. The demand in those companies' areas is still growing at a rapid rate, so it is evident that there is now no difficulty in disposing of as much electrical energy as can be generated from waste heat in this district. The waste heat owner can therefore take advantage of an assured market, and get the current he requires for his own use as cheap as, if not cheaper than, it would cost him to produce it himself—capital expenditure being taken into consideration.

Where ironmaking firms have their blast furnaces situated in proximity to the ironstone, but away from the coalfield, as is the general rule, it may pay to install a coke-oven installation at the ironworks, and dispose of the surplus gas available by a co-operative arrangement. There are arguments in favour of carrying the coal rather than coke from the colliery to the blast furnaces, and a feasible arrangement would be to exchange the surplus gases from the coke ovens at the blast furnaces for a given quantity of electricity delivered at the colliery. It may be argued that the erection of several waste heat stations near the source of waste heat energy defeats the claim put forward as to the advantages to be derived from centralisation. The answer to this argument is that the waste heat stations are run at constant full load, so that there is a very large number of units generated per kw. of plant installed over which to spread the increased capital and operating charges, and, further, that the existence of such stations at different points of the mains network tends to reduce distribution losses. In no case has a proposal on co-operative lines been submitted to a waste heat owner, and carefully considered by him, that has not been ultimately accepted. This fact, together with the general arguments put forward, make out a strong case in favour of co-operation, and the conservation of waste made possible thereby, and if any further argument were needed, it is supplied by the results of co-operation at the Newport Ironworks of Messrs. Sir B. Samuelson & Co., Ltd., and the works of the Weardale Steel, Coal, and Coke Co., Ltd. In the former case the average number of units generated per week during the last few months of last year from the waste heat amounted to over 225,000, of which less than 20,000 were utilised by the ironworks; the rest was distributed by the power company. The amount generated in the latter case averaged at 300,000 units per week, of which about 25,000 were consumed by the works.

In an appendix to the Paper the author dealt with the problem of the method of charging for electrical energy for power purposes. He first emphasised the fact that the price per unit conveys nothing unless accompanied by a definite statement as to load factor, and supplemented by details such as total annual consumption, &c., and that it is only fair, therefore, for the consumer to debit himself with, if he generates, or to pay, if he purchases, a definite lump sum to meet capital charges, entirely apart from the amount of current consumed. These conditions are met by a tariff based on a fixed charge per kw. or electrical h.p. demanded—which demand is not "peak," but an average taken over half-hourly periods—plus a running charge per unit consumed, as, for example, £1 per e.h.p. demanded per quarter, plus 0·3 or 0·25 of a penny per unit. The average price per unit at different load factors under the operation of such a tariff is shown in Fig. 3. This curve shows at a glance what an important effect load factor has upon the average price per unit obtained. If a flat rate of, say, ¾d. per unit were charged, the supplier would lose heavily in the case of a 25 per cent. load factor consumer and the 75 per cent. load factor consumer would pay a most extravagant price. In average cases the tariff quoted would enable the purchaser to secure current at a reasonable price. Where works are situated some considerable distance from the network of mains, and the consumption is variable, it may be necessary to increase both fixed and running charges, whilst in other cases where the rate of consumption is above the average, the running charge may permissibly be somewhat reduced.

ELECTROMETALLURGY

IN the *Iron and Coal Trades Review* of December 24th there is an article describing the installation of the Girod Electric Steel Furnace at Aarau in Switzerland. The plant has been in operation at the works of Messrs. Oehler & Co. since August 1st. The necessary power is supplied by the Aarau Electric Works, which utilise the fall of the Aarau for generating the power. The 2,000-volt two-phase system supplies to a 450-h.p. motor, which runs at 560 revs. per min., and is directly coupled to a single-phase alternator, with an output of from 4,600-5,000 amperes at 65 to 75 volts at 57·4 cycles.

The current is conveyed by 12 copper-wire stranded cables having a diameter of 0·8 in. The drop in E.M.F. from the machine to the furnace is 2·5 volts. The furnace has an inside diameter of 6 ft. 8 in., and is 20 in. high. The electrodes are automatically controlled, so that the strength of the current may be regulated as desired. Each electrode weighs 440 lb., and is 60 in. long. After the addition of the charge of 3,300 lb., and the starting of the current of 5,500 amperes at 55 volts, five hours is required before pouring. At present only two heats per day are run, but there would be no difficulty in running three. The hearth of the furnace is an oblong circular cavity, which when charged has a metal depth of from 10-12 in. The lower electrodes consist of blocks of soft steel bedded in the base of the hearth. These are in direct contact with the molten metal, and form the negative electrode. To prevent them being melted away, there is a water-cooled cavity within them. The current enters the furnace by one or more electrodes suspended just above the molten metal and just dipping into the slag. These are of like polarity, and consequently insulation difficulties in connection with the roof of the furnace through which they pass are obviated.

The Girod furnace is thus an arc and resistance furnace, the arc forming through the slag and metal, and then the current passing out through the iron which thus constitutes the resistance. This arrangement of the electrodes greatly facilitates the starting of a cold charge, because the heating is not local, as is the case with simple electrode furnaces. In starting a cold charge, an arc is first struck between the metal scrap and the electrode, but throughout the charge, wherever the pieces make bad contact, further arcs are produced. Consequently the charge very rapidly melts, and, when melted, becomes coated with the slag, which prevents the action of air. The furnace is also so built as to practically exclude the entrance of the air. The furnace has been found very useful for refining scrap, or for further refining Bessemer steel which is poured into it directly from a Bessemer converter.

For refining a charge of liquid steel from a Bessemer converter, the cost is given as :—

Slaging material	2	0
Electrodes	1	7
Labour	2	5
Upkeep and wear of furnace ...	4	0

Power about 500 kw. hours (according to cost).

With a cold charge of scrap to be completely refined, the charges are :—

Slaging material, 3s. to	3	5
Electrodes	4	0
Labour	4	9
Furnace upkeep and depreciation	12	0

Power, 1,000 kw. hours (price according to circumstances).

In the next number of the same journal a description of the Anderson Electric Furnace is given, which in shape is somewhat similar to the Girod Furnace, but has several special features. It is of the smothered arc type, and is supported on trunnions or bearings in order to facilitate tilting for pouring. The electrodes enter through the furnace cover, and are connected either in parellel or series. Directly below the electrodes and underneath the base of the furnace is a powerful electromagnet, the object of which is to generally control the arc, and so that the incandescent gases round the electrodes may be fully utilised. This is the novel feature of the furnace, and is said to increase the efficiency of the furnace very greatly. A liquid charge can be completely refined in from 60 to 75 min., the average energy consumption being about 280-h.p. hours—a five-ton furnace would require about 800 h.p. For manufacture of steel from ordinary scrap, as soon as the charge has become molten and the slag has formed, an air blast is blown in, the impurities thus become oxidised, and are absorbed by the slag. The slag is then withdrawn, and one or two new slags formed, until the desired degree of purity is obtained. This furnace is suitable for the preparation of high-grade tool and other steels, and for the preparation of alloys.

Electrification of the Prussian State Railways.—According to the *Financial Times*, the electrification of the section of the Prussian State railways running from Magdeburg to Leipsic *via* Halle has been deferred, along with a number of similar projects which have been under the consideration of the Prussian Government. The reason for this step is that the Prussian finances do not at present allow of the expenditure.

THE FULLER INDUCTION MOTORS

THROUGH the courtesy of the Fuller Electrical and Manufacturing Co., we recently had the opportunity of visiting their works at Blackhorse Lane, Walthamstow; and the following brief description of the different patterns of motor manufactured by this firm, and the methods adopted in their construction, may be of interest to our readers.

Asynchronous induction motors of from ¼ to 300 h.p. are manufactured at Walthamstow, and castings and stampings of the best Swedish iron are employed in their construction. Machines of over 300 h.p. capacity are obtained direct from Sweden.

The single-phase motor supplied by the firm is exactly similar in construction to their three-phase induction motor, with the exception of the number of turns and gauge of wire in the different windings. It is wound three-phase, and provided with either a squirrel-cage (short-circuited) rotor, or a wound slip-ring rotor, according to the requirements at starting. When running, two of the three phases are put in series across the single-phase supply mains, and the other is idle. The usual method of starting consists in connecting the third phase between the point of junction of the first two phases and the point of junction of two resistances, non-inductive and inductive respectively, which are connected in series across the supply. By this means phase-displacements between the currents in the three windings, and consequently the necessary rotating field, are produced.

The sectional sketch of Fig. 1 shows the standard construction adopted for all the medium-sized motors; it will be noticed that one wide ventilating duct is provided in the centre of the core body of both stator and rotor. The distance pieces are arranged so as to give a fan action, and by this means a good draught of air through the machine is ensured. Partly closed slots are adopted, and this not only improves the power-factor of the motor by decreasing the mag-

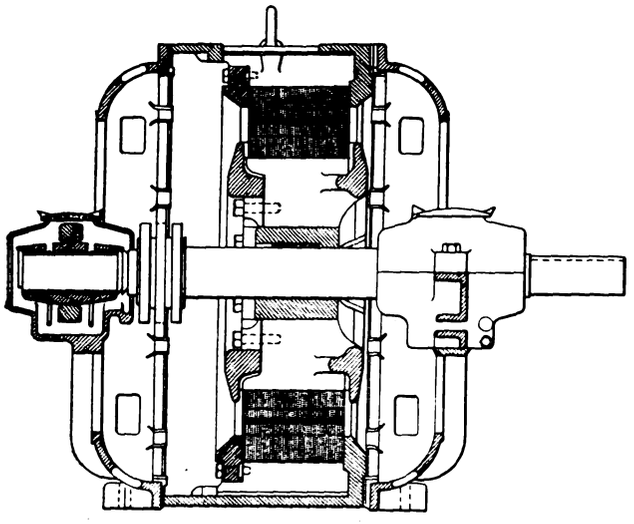

FIG. 1.—SECTION THROUGH STANDARD FRAME OF FULLER INDUCTION MOTOR.

netising current and the magnetic leakage, but also tends towards noiseless running. The slot insulation usually consists of three layers: fibre, mica paper or Empire cloth, and fibre respectively, but in some cases the layer of fibre nearest the iron is omitted. As it is not possible to use former wound coils with partly closed slots, the cotton-covered conductors are pulled through in the usual way. After the winding is completed, the bunches of conductors at the sides are taped and varnished with a waterproof and acid-resisting varnish. All bearings, from the ¼ h.p. size upwards, are supplied with oil rings. The bushings of the smaller motors are of gun-metal, and of the larger motors white-metal. Four different patterns of rotor are employed; the simplest of these is the squirrel-cage rotor, in which the copper rods pass through partly-closed, uninsulated

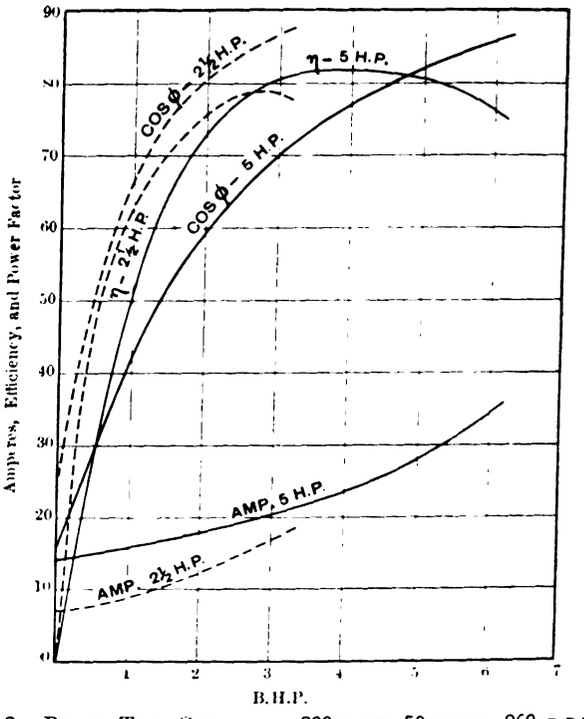

FIG. 2.—BRAKE TEST CURVES OF 200-VOLT, 50-CYCLE, 960 R.P.M. SINGLE-PHASE MOTOR WITH DOUBLE STATOR WINDING.

slots in the core and are both rivetted and soldered to the brass short-circuiting rings. In the larger sizes the rods are insulated from the iron, and in nearly all cases small fan blades are attached to the short-circuiting rings to assist in the ventilation. In another form of short-circuited rotor, the rods are rather longer than usual, and copper wire is interlaced with the ends on both sides. Solder is run all over the wire so that a good electrical contact with the rods is obtained. A spiral of some six or eight turns of wire is wound on at each end, and owing to the excellent cooling conditions these short-circuiting connections can be run at a very high current-density. In some cases, where a motor is to be started frequently and run for short intervals only (so that a high efficiency is not required), eureka resistance wire is used for these connections, with a consequent increase in the starting torque.

The two patterns of wound rotors are the bar-wound and wire-wound respectively. An illustration of a bar-wound rotor with slip rings is given in Fig. 3, and a complete machine with a rotor of this pattern is shown in Fig. 4. For smaller machines in which a wound rotor is required, the wire winding illustrated in Fig. 5 is adopted. An interesting feature of this winding is the method of fixing the end connections. As the wires are pulled through the slots, they are passed through a ring concentric with the core at each end of the armature; there is a separate ring for each layer. This effectually holds the end-connections in position, and prevents movement due to short-circuit or centrifugal force.

With regard to the performance of the single-phase motors, the following particulars of an official test, carried out under the supervision of Mr. P. J. Pringle, Borough Corporation Engineer, Burton-on-Trent, on a 200 volt, 45 h.p. motor, are of interest. The motor is used for driving an air compressor, and is started up

Digitized by Google

by means of a loose pulley. The starting arrangements are the same as those described above, both stator and rotor being wound three-phase. As the comparatively low speed of 540 r.p.m. was required, and the supply frequency was as high as 75 cycles per second, the results obtained were exceedingly good for a single-phase motor. The efficiency at full load was 84 per cent., and the power factor 76 per cent.; at three-quarter load these figures were 84·5 and 75 per cent., and at half-load 82 and 66 per cent. respectively. A five hours' run on a load varying between 35 and 50 h.p., and remaining practically steady at 50 h.p. for the last hour and a half, gave the following temperature rises:—Core, 57° F.; stator coils, 38° F.; and rotor coils, 26° F. When first switched on at starting, the motor took 80 per cent. of full-load current.

In certain cases, where single-phase motors have been required to be run for considerable periods on a fraction of the full load, they have been provided with an auto-transformer in order to obtain higher efficiency and power-factor. To still further reduce the current taken by a motor on low loads, the firm now supply motors which are fitted with two independent stator windings. The results which can be obtained with the aid of such a double winding can be seen from the

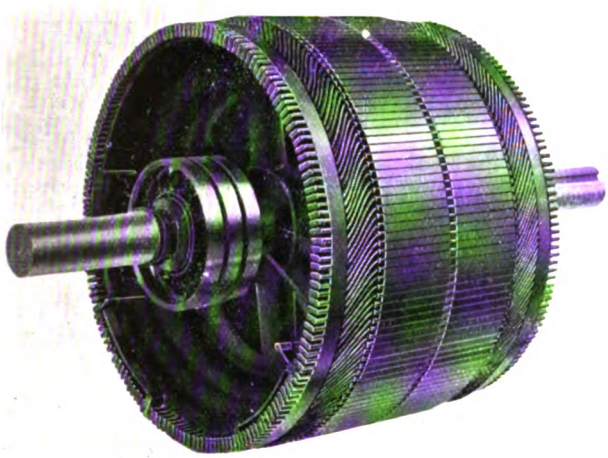

FIG. 3.—BAR-WOUND ROTOR WITH SLIP-RINGS.

performance curves given in Fig. 2. These tests were taken on a 5 b.h.p. 200-volt motor running at 960 r.p.m. on a 50-cycle circuit. The full-line curves show the efficiency, power-factor, and current consumption when the normal (5 b.h.p.) windings are in use, and the broken-line curves show these characteristics of the motor when the auxiliary (2·5 b.h.p.) winding is employed. In certain cases the efficiency on low loads has been increased as much as 10 to 15 per cent., and the power-factor 15 to 20 per cent. by this arrangement.

The cascade arrangement of induction motors in cases where two or more different speeds are required, and which is employed to a large extent on the three-phase locomotives in use on the Continent, is well known, but the following particulars of some rolling-mills equipped on this system may be of interest to some of our readers. The plant in question is that of the Hamilton Steel and Iron Co., Ltd., of Hamilton, Ontario, and is supplied with two-phase current at 66·7 cycles. An 850 h.p. motor drives a 10-inch train through a flexible coupling, and a 14-inch train is driven from this by means of a rope wheel. The main motor is wound for 28 poles, and the auxiliary motor, which is of the squirrel-cage type, is wound for both 6 and 12 poles. Speeds of 200, 235, and 285 r.p.m. are obtained in this way. The actual efficiency curves of the combined motors at the three different speeds are given in Fig. 6. The diameter of the main rotor of the set is about 8 ft., and the total weight of the combined motors is 26 tons. Owing to the facts that the efficiency of the set at the three different speeds

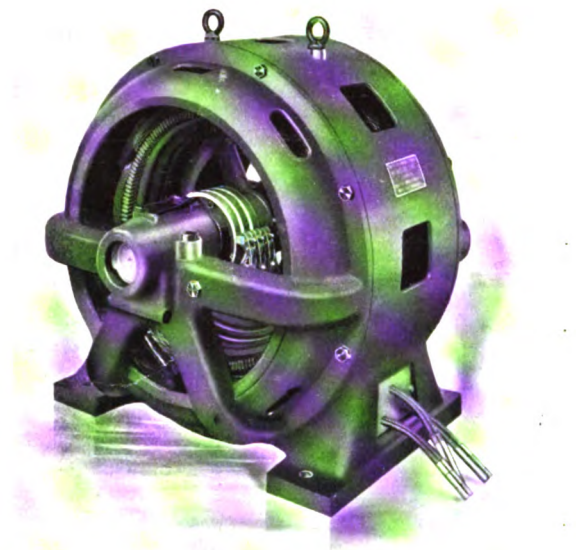

FIG. 4.—COMPLETE MACHINE WITH BAR-WOUND ROTOR.

is approximately the same, and the speed regulation with any one of the three arrangements is very close, the polyphase cascade motor adapts itself very well to this class of work. Furthermore, by the use of a resistance in the rotor circuit of the main motor, at starting, the slip of the motor can be adjusted so as to utilise the flywheel effect most efficiently without any considerable variation in speed. The above set was supplied by the Company in 1904.

A cascade set similar in construction, but with a capacity of only 150 b.h.p., is illustrated in Fig. 7; this set is at work in the Sandviken Iron Works, Sweden, and is supplied with three-phase current at 50 cycles and 500 volts. The three speeds are 428, 375, and 333 r.p.m., and it is further provided with a two-speed pulley, thus making it possible to run the counter-shaft at six different speeds. The efficiencies at full load for the three different speeds were 90, 88,

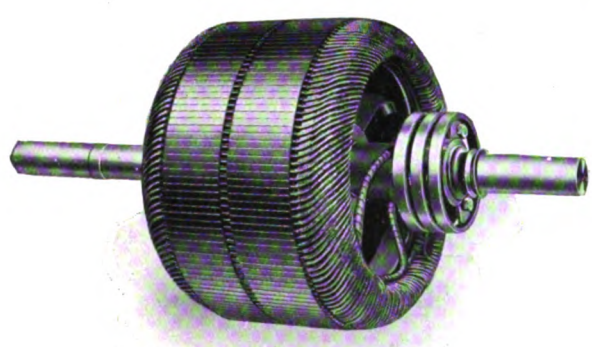

FIG. 5.—WIRE-WOUND SLIP-RING ROTOR.

and 88 per cent. respectively, and the power-factors 92, 83, and 81 per cent.

The rotor starting resistances for the single-phase motors are of the cast-iron grid pattern. The non-inductive resistances used in the stator circuit are of german silver wire wound on asbestos tubes. Besides

Digitized by Google

the single and polyphase motors already mentioned, the firm manufactures alternating-current generators with revolving fields from 6 h.p. upwards; a number of these machines have been supplied to the Marconi Wireless

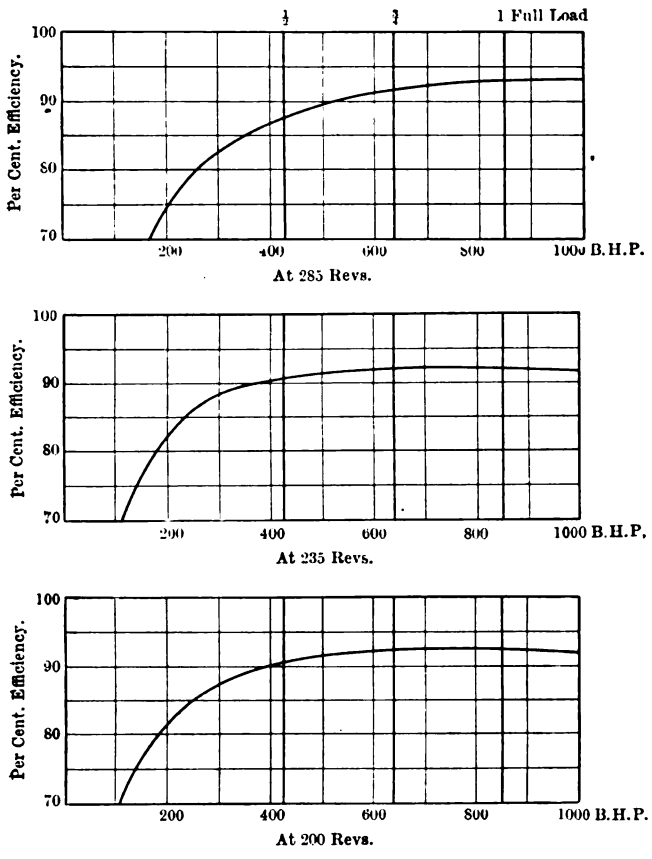

FIG. 6.—EFFICIENCY CURVES FOR ROLLING-MILL TWO-PHASE CASCADE MOTOR.

Telegraph Co., for their wireless stations. For work requiring motors of less than ¼ h.p. capacity, the firm supplies a single-phase motor with a ring wound stator and a short-circuited rotor of the interlaced pattern. To enable the testing of motors of any pressure or frequency to be carried on at the works, three motor-generator sets are installed, and any frequency between 25 and 100 cycles is obtained partly by shunt regula-

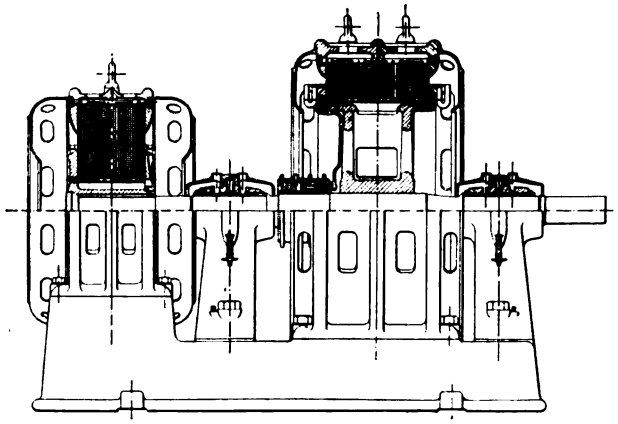

FIG. 7.—THREE-PHASE CASCADE SET FOR DRIVING ROLLING MILLS.

tion of the continuous current motors and partly with the aid of pulleys. In conclusion, we should like to express our thanks to Mr. K. Hedin, of the Fuller Electrical and Manufacturing Co., for showing our representative over the works, and for providing much of the information from which this article was prepared.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

OILS, PAINTS, &c.—We have received several pamphlets from Messrs. Pilchers, Ltd., of Morgan's Lane, Tooley Street, drawing attention to their special "Caroyle" oils for motors and other purposes, and a useful compound, known as "Stoprot," for preventing decay and dry rot in wood. Another speciality is a patent tarpaulin dressing. The lists are accompanied by a tint book of the firm's special paints, showing nearly 70 different shades.

ARC LAMP CARBONS.—A list is to hand from M. Seeck, of 6 Henrietta Street, W.C., of carbons for flame, enclosed, and open arc lamps, manufactured by the Sirius Werke Electrical Carbon Manufacturing Co., of Baden, near Vienna, Austria.

IRON-CLAD SWITCHES AND FUSES.—A list, composed of several leaflets conveniently arranged in a cover, is to hand from Messrs. G. M'Cartney & Co., of Burnside Works, Cumnock, N.B., describing a number of forms of the "Orb" double-, triple-, and four-pole iron-clad main switches, "Orb" fuse-boxes and tubular fuses, complete motor panels, and other switchgear. The "Orb" switches are of the entirely enclosed pattern, with the handle at the side, and are specially suitable for mining and factory work. They have been specially designed to meet the requirements of the Glasgow Corporation rules and nuisance regulations.

INCANDESCENT LAMPS.—A leaflet from Cryselco Lamps, of Kempston Works, Bedford, call attention not only to the well-known British made Cryselco carbon lamps, but also to the new Cryselco metal filament lamp, made for voltages up to 130.

TELEPHONES.—The new revised catalogue of telephone apparatus manufactured by British Insulated & Helsby Cables, Ltd., describes with the aid of excellent illustrations a large range of telephone instruments and accessories. Among these the following may be specially mentioned:—The "radial arm transmitter" enables the height of the transmitter to be varied in such a manner that the transmitter is never tilted, and consequently it remains in the best position for efficient speaking throughout the whole range of adjustment. The "adjustable hand set" has been specially designed to meet the objection to hand sets for common battery working, viz., that the operator's mouth cannot always be brought close to the mouthpiece. The difficulty is overcome by mounting the transmitter and mouthpiece on a sliding bar, and the user, while speaking, can easily adjust the mouthpiece to the best position. Many of the instruments are provided with "detachable switch hooks," which can readily be removed for convenience in packing and to avoid damage in transit. When setting up the instrument it is only necessary to push the end of the switch hook through the side opening; it locks itself in position, and can only be removed by opening the case and depressing one of the switch springs.

CRANE AND LIFT EQUIPMENTS.—A comprehensive catalogue of motors, controllers, &c., for lift and crane work is being issued by Messrs. Marples, Leach & Co. Illustrations are also included of complete electrical travelling pulley blocks, transporters, crates for large travelling cranes, &c.

INDUCTION MOTORS.—Messrs. Marples, Leach & Co. have sent us a copy of their revised list of single-, two-, and three-phase induction motors, which contains a very complete range of short-circuited and slip-ring motors and accessories.

TRANSFORMERS.—A new pamphlet, giving prices and particulars of the small transformers in which the Foster Arc Lamp & Engineering Co. have so successfully specialised, is being issued. The sizes listed range from 5 to 100 amperes for various periodicities and voltages. All these standard sizes can now be delivered from stock as auto-transformers, and special double-wound transformers up to 30 kw. can be supplied to order. Among the features of the design are the use of a patent heat-conducting and fire-proof material between the windings, and the fact that the iron used is non-ageing.

ARC LAMP ACCESSORIES.—Messrs. J. & H. Grevener, of Eldon Street House, E.C., are issuing a very complete catalogue of arc lamp accessories, couplings, winches, pulleys, &c., embodying a large number of special designs of this class of apparatus.

POCKET-BOOKS, DIARIES, &c., FOR 1909.

Messrs. Pilchers, Ltd., of Morgan's Lane, Tooley Street, S.E., manufacturers of paints, &c., suitable for engineering purposes, have sent us a handy pocket almanac and diary, containing a quantity of useful information.

The large wall calendar for 1909 which is being issued by the Phœnix Dynamo Manufacturing Co., of Thornbury Works, Bradford, is executed with an artistic colour scheme, and contains representations of various types of machine manufactured by the firm.

An artistic calendar, with interchangeable cases for the days of the week and the months themselves, is being sent out to their friends by the Western Electric Co., of North Woolwich.

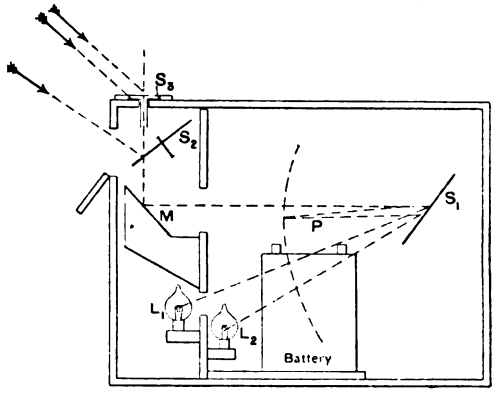
Digitized by Google

Views of up-to-date telephone apparatus and sections of cables remind us of the range of manufactures of the firm.

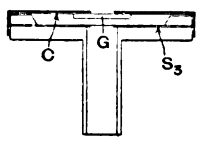
A neat paper-weight, in the form of a miniature reproduction of the "Orb" iron-clad switch, with handle at the side, is being presented to their friends by Messrs. G. M'Cartney & Co., of Burnside Works, Cumnock, N.B.

The Brush Electrical Engineering Co., Ltd., have issued a most artistic tear-off daily wall calendar, with a three-colour reproduction of a painting representing a foundry scene by Mr. E. R. Fox.

TRAMWAYS AND LIGHT RAILWAYS IN THE UNITED KINGDOM



THE Board of Trade have issued a return of street and road tramways and light railways authorised by Act of Parliament or otherwise, showing the amount of capital authorised, paid up and expended, the length of line authorised and the length open for public traffic down to December 31st, 1907, in respect of companies, and March 31st, 1908, in respect of local authorities. The return also contains a large amount of statistical information on other matters in relation to tramways and light railways. A comparative table shows that since the year 1878 the route length of line open for traffic has increased from 269 miles to 2,464 miles; the capital expenditure from £4,207,350 to £68,199,918; the number of passengers carried from 146 millions to 2,626 millions; and the net receipts from £230,956 to £4,646,962. More detailed comparisons between the year 1878 and the year 1907-8 will be found in the table mentioned. The number of passengers carried in the year is equal to about 60 times the estimated population of the United Kingdom. Of the total of 1,620 miles of line owned by local authorities, 1,461 miles are worked by those authorities themselves, and the remaining 159 miles by leasing companies. Last year the route mileage open of electric line was 2,195 miles out of a total of 2,394; this year it is 2,286 miles out of 2,464. The mileage worked otherwise than by electric traction has further diminished from 199 miles to 178 miles. Of the 305 undertakings, 177 belong to local authorities and 128 to companies or other parties. Local authorities who work, as well as own, their tramway undertakings have made a net profit of £3,286,713 on the year's traffic, out of which they have applied £916,291 towards the reduction of tramway debt and £319,676 in relief of rates, while carrying £728,653 to reserve and renewal funds. In the cases of three local authorities and seven companies, the returns show an excess of working expenditure over gross receipts. With regard to the appropriation of net receipts, it is explained that in many instances the figures will not correspond with the municipal or company accounts for the year. The return has been restricted to showing the disposal of the net receipts earned during the particular year, whereas the accounts would include moneys brought forward from a past year or derived from other sources, including (in the case of some local authorities) the local funds. Other statistics taken from the report, applying to the whole of the undertakings in the United Kingdom, both municipal and company, for the periods mentioned above, are as follows:—Gross receipts, £12,439,625; total working expenditure, £7,792,663; number of passengers carried, 2,625,532,895; number of car miles run, 282,588,392; quantity of electrical energy used, 431,969,119 Board of Trade units; number of electric cars in stock, 10,908.



Telegraph Traffic.—Telegrams for Messina are still only accepted at senders' risk, but messages for Catania and Syracuse can be accepted without restriction by the Eastern Telegraph Company's route. The French Company's cable between Martinique and Paramaribo is down, as is also the cable of the West India and Panama Telegraph Company between Jamaica and Colon. The Medang-Penang and Malta-Zante cables have not yet been repaired, and the Pontianak-Saigon cable has also not yet recommenced operations.

New German South Atlantic Cable.—In ELECTRICAL ENGINEERING, Vol. IV., page 376, reference was made to the formation of the Deutsch Süd-amerikanische Telegraphen-Ges., in Cologne, for the purpose of laying a submarine cable to connect up Germany with her colonies. According to the *Standard*, the first section of this cable, from Borkum, in the North Sea, to Teneriffe, will be laid this year. Permission to establish a station at Teneriffe has been granted by the Spanish Government. The cable will probably touch at Monrovia, the capital of Liberia, and from thence run direct across the southern Atlantic to Pernambuco. The total length from Borkum to Pernambuco, by way of Teneriffe and Monrovia, is approximately 7,000 miles. It is anticipated that the last section, from Monrovia to Pernambuco, will be completed early in 1910. As we mentioned in our previous note, the German Government have granted the company a subvention, and German commercial firms established in South America have promised active support to the enterprise.

THE HARRISON UNIVERSAL PHOTOMETER

THE latest form of the Harrison Universal Photometer, manufactured by Messrs. Elliott Bros., has recently been considerably improved by the addition of a simple attachment that enables the horizontal illumination from all sources to be measured. The instrument is intended for the measurement of illumination on a screen making an angle of 45° with the vertical, and for the measurement of the candle-power of various sources of light. It is provided with a flicker disc rotated by a blast of air under the control of the operator. By fixing the flicker disc to half cover the field of view of the eye-piece, the instrument may be used as a direct comparison photometer, the illumination of the source of light being compared directly with

S_1. Adjustable screen, attached to pointer.
P. Pointer on outside of case.
S_2. Revolving sector screen for general illumination.
S_3. Screen for horizontal illumination.
M. Reflecting Mirror.
L_1, L_2. Standard lamps.
C. Cover cap, to be removed when taking horizontal illumination.
G. Glass in eye-piece.

IMPROVED FORM OF HARRISON PHOTOMETER.

that of the adjustable screen inside the instrument, illuminated by a small standard lamp connected to a self-contained accumulator battery.

The recent addition to the instrument consists of a horizontal screen, which is covered by a cap when the flicker disc is used. This cap has a hole through the centre, and forms the eye-piece of the instrument. When the cap is removed the horizontal screen is exposed, and by fixing the flicker disc out of the field of view of the eye-piece, by means of a small milled-headed screw, the photometer can be used to measure horizontal illumination by direct comparison. The accompanying figure gives a general diagram of the instrument, together with an enlarged view of the eyepiece, which will make the construction quite clear.

The illumination to be measured is in all cases read off directly on the scale by means of the pointer, which is fixed to the adjustable screen mentioned above, and by moving which a balance is obtained between the illumination of the source of light under test and that due to the small standard lamps inside the instrument.

From the foregoing it will be seen that the following tests can be made with the instrument:—Candle-power by means of flicker disc; candle-power by direct comparison method; illumination on screen at an angle of 45° by flicker disc; illumination on screen at an angle of 45° by direct comparison method; horizontal illumination by direct comparison.

The original features of the instrument have all been retained, and the new model is just as simple to manipulate as the older pattern, and among advantages possessed by the instrument are light weight and portability, and long range due to use of two standard lamps of different candle powers. Permanent connections are made between battery and rest of circuit, which need never be disconnected for charging purposes, and the battery, standard lamps, and flicker disc may be readily removed from instrument for inspection, without disconnecting or altering any adjustments. Easy and accurate manipulation is secured due to arrangement of pointer screen and flicker disc. We may mention that the addition of the horizontal attachment does not increase the cost of the instrument, owing to its simple construction and method of manufacture.

Wireless Telegraphy in the Navy.—According to the *Naval and Military Record*, the New Year promotions were telegraphed by wireless telegraphy from Whitehall to the various naval centres. At Devonport the messages were received by the battleship *Queen*, which is fitted with the latest pattern of apparatus. It is also stated that the Hornsea wireless station in Portsmouth Harbour is being enlarged in order that the number of operators in training may be increased, as a number of new Admiralty stations are to be erected round the coast.

CORRESPONDENCE

(*Continued from p.* 31.)

THE REGULATION OF ARC LAMPS WITH CONVERGING CARBONS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to Dr. Teichmüller's article abstracted in last week's ELECTRICAL ENGINEERING, I agree with your own remark that the results obtained by those commercially interested in flame lamps are not widely circulated. Naturally, they are only of interest really to other manufacturers; users would not be concerned, and the scientific interest is, in a sense, unimportant. With regard to the article itself, I should disagree that the magnetic "blow" in itself has any effect whatever on the "regulation" of the arc. I further do not think that the question of magnetic blow is in any way complicated, or that there is any necessity for elaborate presumptions with regard to its behaviour or usefulness; such can generally be surmised and often claim attention whilst the real facts are absolutely simple.

In many ways, in my opinion, it is quite immaterial whether "blow" is used or not, and in any case it is only useful as a matter of convenience; further, the less "blow" that is used, or necessary, as the case may be, the better. I may mention that we make identical lamps to work under slightly varying conditions, both with and without "blow." I do not find the difference referred to between large current and small current arcs, at any rate, between 6 to 12 amperes. I also think that "sensitiveness" is not exactly the right word to use in comparing converging and vertical arcs in the commencement of the second paragraph. If sensitiveness is intended, I do not agree that the converging carbon arc is more sensitive than the vertical flame arc.

The remarks respecting "overfeed," due to inequalities of impregnating materials, I agree with, but I believe that "blow" in itself has nothing to do with steadying the burning of the arc as suggested. The greatest improvement we have made in our lamps lately has been in this direction, *i.e.*, to arrange a mechanism which is unaffected by the temporary variations of the carbons, which enables us to use cheap qualities of carbon amongst other advantages.

The 84-volt arc experimented with would not be a practicable example, and the large-voltage arc would introduce peculiarities of its own which would not exist in an ordinary, say, 42-volt, arc.

In conclusion, I should say that the variations with sensitive meters of current and volts in a given lamp with different carbons would be a simpler test for quality of carbons. With regard to testing lamps it is more difficult, perhaps the most regular lighting effect multipled by unlikelihood of getting out of order is the best criterion in a flame lamp. Steadiness of current and volts with given carbons is of some use—feed alone as generally specified is ridiculous. The lighting effect at some stage of the carbon may be quite as good at 35 volts and a given current as at 45 volts at another stage, so that the voltage is not necessarily always a criterion of the virtue of the lamp, and following it too closely might lead to unnecessary instability, but a good lamp should always keep its current as exact as possible.

Yours faithfully,

Gilbert Arc Co., Ltd.,
Chingford, Essex, Jan. 11th, 1909. C. GILBERT.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Referring to the article by Dr. Teichmüller and the Editorial, in your last issue, the arrangement of converging carbons has been developed more from the necessity of slag prevention than the need of a better distribution of light. The original Bremer arc lamp was the first lamp in practice to use chemically impregnated and converging carbons. The carbons in these lamps often produced so much slag that even with the converging pattern a knocker or vibrating armature was often arranged in order to restrike the lamp.

Most of the flame carbons at present in use with open-type flame lamps have the chemicals contained only in the core, the outer sheath of carbon being of pure, or nearly pure, carbon.

With the improved mixtures in the present flame carbons the slags run to the ends of the carbons (*i.e.*, they remain near the cores), and the converging arrangement allows contact to be made on the clean and pure carbon at the sides.

The distribution of light with converging carbons gives the maximum intensity immediately below the arc, resulting in that patchiness of illumination usually seen with converging carbon flame arcs. I have found that steadiness with converging carbons and a blow-out magnet is dependent upon a field sufficiently strong to maintain the arc constantly at the carbon ends, centralising the arc upon the core of the carbons; while, at the same time, the arc in its normal position must not enter a field strong enough to approach the magnetic density at which the arc will be ruptured by the magnetic action of the blow-out.

Provided this field is moderately well shaped, and about the right strength, it may be produced in many ways, and—as you point out in your Editorial—both very elaborate and very simple and apparently haphazard arrangements work equally well. If a large amount of iron is near the arc, this may be sufficiently magnetised by the current flowing through the carbons to act as an efficient blow-out magnet. Blow-out magnets are often series, shunt, and even compound wound. All of these act efficiently, if the strength of field in the normal arc position is within the limits I have mentioned. A field that varies rapidly in intensity may give perfectly good results, provided the arc is maintained within narrow limits of space; while a field varying slowly in intensity with well-spread magnetic lines will give good results even with an arc that is allowed to vary its position.

In an arc lamp in which the carbons are fed forward by mechanical means, such as fusible or combustible stops, it is possible, by properly proportioning the strength and distribution of the magnetic blow-out field, to obtain a regulation equivalent to the retractile feed of a series or compound solenoid controlled lamp. An increase in the arc voltage will then lead to a small increase in current, which is sufficient, if the field is properly proportioned, to blow the arc out to a longer curve, thus increasing the resistance of the arc and reducing the current to very nearly its original value.

The over-feeding mentioned by Dr. Teichmüller should not be possible with a well-designed lamp. Over-feeding really means that the mechanism allows the carbons to be fed forward or to slip forward to a greater extent than can be afterwards retracted by the mechanism. A good modern arc lamp should have a retractile feed of sufficient extent to allow any forward movement of the carbons to be entirely neutralised by a corresponding backward movement. If the retractile feed is insufficient in amount, unsteadiness will be produced by any variation in the voltage or the quality of the carbons. "Overfeeding" is distinctly a mechanism fault, and more often a fault of design than a fault from failure of mechanism or dirt in the lamp.

This retractile feed is difficult to obtain in a lamp of the converging pattern without moving the arc very considerably from its normal burning position, and movement of the arc from its normal position will often result in fluctuation of the light due to the alteration of the strength of the blow-out field.

I remain, sir,

Yours faithfully,

A. DENMAN JONES.

The Jandus Arc Lamp and Electric Co., Ltd.,
Holloway, January 11th, 1909.

ICE-MAKING PLANTS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—In your issue of the 7th inst, you publish an article on "Ice-making Plants for the Improvement of the Load Factor." It is some years since I was connected with the ice-making and refrigerating industry, and I cannot at the moment put my hand on the data, &c., I collected while I was in that line, but a few facts I remember may interest you. Most of the ice in this country is made on the cell system, though the latest plants seemed to favour the can system, using distilled water. The cell system seems to be extremely like the grid system described by the writer in the *New York Electrical World*. You will see this system at United Carlo Gatti, Stevenson and Slater's places at North Road, Holloway, and Park Road, Battersea. With a 40-ton plant on the cell system I was connected with some four or five years ago at Southampton, we made 12 in. ice in 7½ cwt. blocks in 64 hours. It took this time to get the air out, so as to form clear, hard ice. When the ice was required for crushing purposes (for insulated railway trucks), and it was not necessary to have it free from air, the ice could be made in about one-third the time. This plant was originally steam driven (it was, in fact, the plant from the old ice-skating rink in Brighton), but recently the proprietor, Mr. Gough, put in suction-gas plant to drive it. When this is in proper working order they can turn out 19 tons of ice daily on 15 cwt. of coal, so that is better than the 14 tons of ice for 1 ton of coal of the American plant.

It is perhaps not generally known that the Eccleston Place station of the Westminster Electric Supply Co. was originally run in conjunction with an ice-making plant.

Yours faithfully,

GEORGE P. LEE.

Tooting Bec, January 11th, 1909.

LOCAL NOTES

ABERDEEN: *Electrical Heating and Cooking Apparatus.*—At the last meeting of the Corporation, it was reported that the Electricity Committee had instructed the Electrical Engineer to procure a stock of electrical heating and cooking apparatus for hiring out. Objection was taken to this on the ground that it was interfering with the business of private traders, but it was pointed out that this principle of hiring out apparatus had been applied by the gas department for some time. Treasurer Meff urged that the position of trade in Aberdeen was such that the Council should do all that was possible to encourage private traders, and not to compete with them, and he proposed a resolution deferring consideration of the question for three months, in order to give the private traders an opportunity of providing the necessary stock of heating and cooking apparatus. The resolution was carried by 17 votes to 14.

ARBROATH: *Assessment of Telephone Co.*—The Parish Council has acceded to a request by the National Telephone Co. for a rebate of 35 per cent. on the assessment of their undertaking in the district.

ARGENTINE: *Cordoba.*—The electrification of some of the tramways in the city of Cordoba has, says the *Review of the River Plate*, been commenced.

BATH: *The Electricity Works Sale.*—Mr. Schenk, who, it will be remembered, has been in negotiation with the Corporation for some time with regard to purchasing the municipal electricity works, the sale of which was vetoed by the Board of Trade, has requested an interview with the Electric Lighting Committee before the deputation from the Corporation waits upon the Board of Trade in regard to the sale. Mr. Schenk has been informed that the Electric Lighting Committee think it better in all interests that the interview with the Board of Trade should take place before the committee meet him. The Board of Trade has expressed their willingness to receive the deputation from the Corporation very shortly.

BELFAST: *The Abbey Sanatorium.*—At the weekly meeting of the Electrical and Tramways Committee on the 11th inst., a deputation attended from the Belfast Board of Guardians relative to the electric lighting of the Abbey Sanatorium, Whiteabbey. The deputation wished to know if the Corporation would put down the cable and supply the current. It was pointed out that the loss in transmission would be so excessive as to make the cost prohibitive, but eventually it was intimated that if they desired to go on with the matter the Corporation would give every facility. The distance is about seven miles from the power station.

BIRMINGHAM: *High-tension Consumers' Dinner.*—An interesting event took place on Tuesday, the 5th, when the representatives of electrical contracting firms gave a dinner to the Birmingham manufacturers who are taking high-tension current from the Corporation mains. The contractors concerned (British Westinghouse Co., Ltd., Siemens Bros., Ltd., General Electric Co., Ltd., and British Insulated & Helsby Cables, Ltd.) generously invited the Corporation engineers to join them, and the chair was occupied by Mr. W. E. Milns, of the Birmingham Corporation. Speeches showed that the very best feelings existed between the consumers, the electrical contractors, and the Corporation engineers, and, in emphasising this, Mr. Milns pointed out that it was the result of the Corporation's endeavour to conduct the undertaking on sound and straightforward lines, and to conscientiously consider the interests of the consumer. He also attributed this friendly feeling to the personality of the leading Birmingham manufacturers, and spoke highly of the plant supplied by the various electrical firms. The good fellowship existing was such that the party did not break up until 5 a.m. on the following morning.

BRADFORD: *Electricity Extensions.*—The scheme of extensions prepared by Mr. T. Roles, the City Electrical Engineer, and outlined in our issue for December 17th, has been adopted by the Council.

Superannuation of Tramway Employees.—A sub-committee has been appointed by the Tramways Committee to go into the question of the superannuation of the tramway employees.

Electric Supply Area.—The Shipley Urban District Council have asked that, as regards the Corporation's application in the Bill deposited for next session for powers to supply electricity in bulk to neighbouring authorities, the district of Baildon should be excepted, the Shipley Council being of the opinion that they, as owners of the right to supply gas in the Baildon area, should have the first right to supply electricity. On the recommendation of the Parliamentary Committee, however, the Corporation have decided to retain the wording in the Bill as it stands at present, which is in general terms and does not refer to any specific area.

BRAUNTON (NORTH DEVON): *Electric Supply.*—Arrangements are being made to form a local electric lighting company with a capital of about £3,000. It is proposed to establish works on the site of the present pumping station belonging to the South-Western Railway Co., and the promoters have discussed an arrangement with the former by which, in return for certain services from the electric light works, a substantial yearly contribution will be made by the railway company. The scheme provides for public lighting. In the matter of private lighting, it is intended to adopt the system of fixed charges, and the figure of 8s. per annum for each 32-watt lamp is mentioned. Meters, however, will be installed where desired.

BRISTOL: *Corporation and Power Co.*—Under the Somerset and District Electric Power Co.'s Act of 1903, a period was stipulated within which the company might start operations within the city of Bristol. This period, however, expired some time ago, and the Corporation applied to the Board of Trade to receive a deputation to urge that an order should be made officially stating that the company's powers of competition in Bristol should cease. A reply has been received from the Board of Trade, however, to the effect that on Thursday last such an order was made by the Board, and that in consequence it is unnecessary for a deputation from the Corporation to come to London.

BURTON-ON-TRENT: *Tramways.*—The negotiations with the Midland Railway Co. for a lease to them of the tramways from the boundary of the borough to the junction of the Church Hill Street are now practically completed. An annual rent of £825 is to be paid, together with 1·3d. for each unit of energy supplied to the company for 21 years, with an option to the company for a further period of 21 years. Running powers are to be given over the Corporation tramways to Wellington Street for a similar term, subject to the payment of 4½d. per car mile.

CANTERBURY: *Accident at Electricity Works.*—One of the labourers at the electricity works last week fell from a ladder which was placed upon the travelling crane for the purpose of cleaning the windows, and died shortly afterwards.

CARDIFF: *Street Box Explosions.*—The covers of no less than nine of the Corporation electricity street boxes were blown off on Sunday afternoon through gas explosions, but fortunately nobody was injured. It appears that since Friday a gang of the Gas Company's men have been searching for a leak in a 6-in. gas main in the vicinity, and it is quite clear that the gas had entered the street boxes and become ignited.

CHELTENHAM: *Electricity Accounts.*—The accounts of the electricity undertaking for the past year show receipts of £23,162, and expenditure of £9,870. The financial charges totalled £10,416, leaving a net profit on the year's trading of £2,691. The chairman of the Electricity Committee states that had the concern been run by a public company, it would have been in a position to pay a dividend of 6 per cent., and carry forward £2,000 or £3,000 to the reserve fund. The first charge upon the net profit is the payment of a proportion of the principal and interest of the debt which was piled up during the earlier years of the undertaking. This absorbs £2,051, leaving £641, to which had to be added £472 brought forward from last year. Out of this £1,113, the committee propose to put £700 to the reserve fund (increasing it to £2,700), and to carry forward £413 to next year's account. For the first time in the history of the concern the revenue had not shown expansion. This was due to the introduction of the new metal filament lamps. The number of customers, however, has increased. The accounts have been referred back, in order to give the Finance Committee an opportunity of considering them.

CHIPPING NORTON: *Electric Lighting.*—The Council has under consideration an application by the Chipping Norton & District Electric Light & Power Co. for an electric lighting Provisional Order.

CROYDON: *Tramway Employees' Sick and Benefit Society.*—The annual general meeting of this tramway society was held recently at the Thornton Heath depôt. Mr. T. B. Goodyer, the general manager, presided. The contributions to the society are based on a weekly payment of 1s. 1d., which entitles the members to sick-pay allowances at the rate of 20s. per week for a period of thirteen weeks, and also free medical attendance. In reviewing the work of the society during the year, the president stated that the audited accounts showed the total contributions to have amounted to £400 10s. 2½d., a reduction of £72 compared with the previous year, due, unfortunately, to the fact that the society contained less membership, the average for the year being 133, against 163 in 1907.

DROYLSDEN: *Electricity Supply.*—The Manchester Corporation, which has electric supply power in Droylsden, is endeavouring to find out the possible number of consumers before proceeding with the work. Apparently, the local council is apprehensive that if the result of the canvass is not satisfactory, the Manchester Corporation will not proceed with the work, and have given a hint to the Corporation that under their Parliamentary powers they are compelled to give a supply.

DUBLIN: *Tramway Fares.*—The Dublin United Tramways Co. have intimated to the Corporation that they are unable to fall in with the suggestion contained in a resolution recently passed by the Corporation that children should be carried at half fares. A resolution by Mr. P. T. Daly has been passed by the Corporation referring the decision of the company to a committee of the whole Council, to see if they cannot compel the company to adopt the suggestion in question. One councillor

Digitized by Google

in the discussion reminded the Council that the company paid £10,000 as wayleaves, and that it seemed unfair to press the resolution.

DUNDEE: *Charge for Tramway Current.*—Through the courtesy of Mr. H. Richardson, the Borough Electrical Engineer at Dundee, we are informed that the charge for tramway current there is not in any way in dispute. The notes on this subject which appeared in our last two issues related to another town, but were inadvertently headed "Dundee," and we regret the error.

Tramway Receipts.—During the twelve months ended December 31st, 1908, the number of passengers carried upon the Corporation tramways was 16,553,057, and the receipts £61,514. The number of car miles run was 1,334,003, these figures constituting a record for the undertaking.

EDINBURGH: *Action re National Exhibition.*—An action was heard at the Sheriff's Court last week in which the General Electric Co. claimed payment of £267 17s. 7d. from Messrs. Pratt Bros., electrical engineers, Dalry Road, Edinburgh, for goods supplied and delivered. It appears that the plaintiffs supplied electric lamp-holders and lamps to the defendants for use at the Scottish National Exhibition, but that dissatisfaction was expressed with them on the ground that they were not "Robertson" lamps. The plaintiffs contended that the lamps supplied were "Robertson" lamps made at the Robertson factory, and that, although subjected to considerably rougher treatment than was usual with electric lamps, they stood the test with a smaller percentage of breakages than was usual in similar circumstances. The defendants contended that they had no alternative than to use the lamps supplied, owing to the time for the fulfilment of their contract with the exhibition executive being limited, but they estimated loss to the extent of £50. Judgment was given for the defendants for damages of £39, the Sheriff not being satisfied that an agreement had been made that the lamps should not be stamped with the "Robertson" trade mark. The defendants were also granted a deduction of £5 7s. 10d. discount and four-fifths of the costs of the action.

EPSOM: *Electricity Undertaking.*—As a result of certain irregularities which have been discovered in connection with the wages and cash books at the electricity works, proceedings have been taken against the office clerk, who has been permanently discharged from the Council's service. A special committee was then appointed to continue the investigations of the books and accounts, and with power to control the management of the electricity department for the present. It is now suggested that the accounts and books of the electrical undertaking for the period from April 1st, 1907, to September 30th, 1908, be examined by a firm of accountants, and the Council has agreed to this.

FALKIRK: *High-tension Overhead Wires.*—The Town Council has approved of the erection of a high-tension overhead line by the Scottish Central Electric Power Co.

GLOUCESTER: *Coal Costs.*—It was stated at the last meeting of the Corporation that the coal costs at the electricity works were very considerably less under the new contracts, being 0·25d. per unit, as against 0·44d. per unit last year and 0·306d. in the preceding year.

HESSLE: *Electric Lighting.*—The Board of Trade have agreed to defer the question of revoking the Council's Electric Lighting Provisional Order for twelve months. It will be remembered that the question of a supply being given in Hessle by the Hull Corporation is receiving attention.

JOHANNESBURG: *The Electric Power Plant.*—The work of erecting the new electric plant at the power station, says *South Africa*, is well forward, and is probably running by now. Messrs. Reunert & Lenz secured the contract for the supply and erection of a 1,000-kw. direct-current plant to augment that already in use. This new engine will supply power for the tramways and for the lighting of the central portion of the town. It is a Belliss & Morcom engine, direct coupled to an A.E.G. dynamo, the engine being a replica of the two sets installed at the power station during the last twelve months. There is also a 500-h.p. boiler, fitted with a Babcock & Wilcox chain-grate stoker, together with exhaust piping and condensing plant. The first part of the engine arrived at Durban by the *Inanda* on November 22nd, and was delivered in Johannesburg five days later. The dynamo arrived by the *Briton* on November 29th, and reached Johannesburg on December 4th. The remainder of the engine was due to arrive at Durban by the *Umtata*.

KALGOORLIE: *Electric Supply Statistics.*—Reporting upon the municipal electric supply undertaking for the year ended October 31st, 1908, Mr. D. Curle Smith, the electrical engineer, states that the output was 1,004,007 units, as against 958,943 for the previous year, an increase of 4·7 per cent. The number of units sold was 793,837, as compared with 784,295 last year, an increase of only 1·2 per cent. The discrepancy between the extra units generated and sold is accounted for principally by the fact that the accumulator has been in use the whole of the year under review, while it had only been in use for six months of the previous year; consequently the loss due to the transformation of energy has continued for double the time this year that it did last year, and is, therefore, greater. Although the units sold are somewhat greater in number this year, the revenue collected from the sale is somewhat less, due to the fact that a bigger proportion of low-priced units has been sold this year than last, the figures being £18,728 for last year, as against £18,491 for this year. The working costs have, however, been reduced in a still greater proportion, so that the gross profit is larger this year than last, the figures being £11,477 last year, as against £10,679 this year, a reduction of £798, in spite of the fact that fuel is 1s. per ton dearer this year, which represents an increase in costs of £366, so that but for that increase the saving in working expenses would have been £1,164. The gross profit for the year is £7,812, compared with £7,251 for the previous year.

LAUNCESTON (Tas.): *The Electricity Works.*—Reporting upon the municipal electricity undertaking, the Mayor states that it will be necessary, if the business is to expand, to erect more machinery to meet it, and, with a view to coping with additional business in the future, the city engineer and the city electrical engineer have been instructed to report as to the maximum economical power to be obtained from the river. He goes on to say that had a company supplied the street lighting, the cost to the city for an equivalent service as now supplied would be over £5,090 per annum, instead of, as at present, a little over an average of £2,000 per annum. The department thus made the citizens a gift of £3,000 a year, equal to about a 5d. rate.

LEEDS: *Tramway Receipts.*—The total receipts from the tramways undertaking for the 37 weeks of the present financial year amounted to £263,943, compared with £260,802 for the corresponding period of the previous year.

LONDON: *Hammersmith Tramways.*—The Borough Council has unanimously decided to oppose the proposal contained in the London County Council's Tramway Bill for next session to construct temporarily a tramway line across Hammersmith Broadway, connecting the line from Willesden with the new line between Hammersmith and Putney. The Council has the greatest objection to tramcars running across such a busy thoroughfare as the Broadway until the necessary widenings are completed.

Islington: The Electricity Staff.—The staff of the electricity works held their annual dinner on Saturday, Mr. Albert Gay, the Chief Electrical Engineer, being in the chair. In the course of some remarks, Mr. Gay took the opportunity of mentioning the fact that the ring mains system, which had been made such a special feature in the big power schemes in London recently before Parliament, had been adopted in Islington in 1893.

St. Pancras.—The Works Committee of the Borough Council recommends that the request of the London County Council for the narrowing of the footpath on the west side of Kentish Town, so as to admit of a double line of tramways, be not agreed to, having regard to the safety of the public. With regard to the proposed widening of Fortess Road, the Borough Council is recommended to decline to make any contributions towards this, but to offer facilities, as the trustees of one-third the property of Fortess Terrace, for the acquisition by the Council of the freehold land required for the widening. The reconstruction of the tramways in King's Cross Road meets with the approval of the Works Committee.

LOUGHBOROUGH: *Expert's Report.*—The report upon the financial and general position of the electricity undertaking by the independent expert will be presented to the Corporation very shortly, and, in view of this, the consideration of the accounts for the past year has been deferred. The total expenditure during the half-year to December 31st upon the electricity undertaking was £1,410 5s. There was a loss on the half-year's working of £144.

LYME REGIS: *Electric Lighting.*—The scheme of electric lighting, which has been placed before the Council on behalf of a private company, has been provisionally agreed to.

MACCLESFIELD: *Electricity Supply.*—The Council has considered the notice of an application to be made to the Board of Trade by the Macclesfield Electric Lighting & Power Co. for an electric lighting Provisional Order for the district. A committee has been appointed to go into the question of whether the Council should own the electrical undertaking itself, and meanwhile opposition will be made to the proposal of the company. About three years ago a Local Government Board inquiry was held as to an electric lighting scheme then put forward, which was found to be altogether inadequate. The Corporation has a Provisional Order from the Board of Trade which it agreed to dispose of for £650 to a company undertaking to introduce electricity, but this arrangement fell through, and for three years the whole question has remained in abeyance.

MAIDSTONE: *Electricity Loan.*—The Local Government Board have communicated with the Council with regard to the recent application for sanction to borrow £20,770 for electric supply purposes. The letter in question states that from the inspector's report there has been excess expenditure amounting to £5,559 on works, &c., in respect of which sanction to loans had been previously granted, including excess of £3,160 on account of the works for which the original loan of £38,048 was sanctioned in November, 1900. This excess expenditure had been met out of monies borrowed subsequently, and as all the loans had been placed to common funds, and used for the various purposes of the undertaking without proper accounts being kept

Digitized by Google

of the expenditure under each loan, the result was that the Council was not now in a position to show precisely the expenditure under particular items for each loan. The letter further referred to the fact that the Council has within the past two years incurred expenditure on new works and machinery amounting to £9,761, in anticipation of a loan, notwithstanding the warning given by the Board on May 22nd, 1905. The attention of the Council is further called to the fact that motors have been purchased and let out on hire, and that the wiring of houses has been undertaken without statutory powers, and that the money to meet this expenditure has been obtained by means of an overdraft on the borough treasurer. The Local Government Board considers the proceedings in these matters very unsatisfactory, and before sanctioning any further loans asks for an assurance that similar irregularities will be avoided in future and that proper and separate accounts of the expenditure under each loan will be kept. The Local Government Board also request the Town Council to submit proposals for paying off the overdraft on account of the illegal expenditure on motors and free wiring within a shorter period than seven years. At the meeting of the Council last week, it was stated that the illegal expenditure on motors and wiring would be paid off in three or four years, and the requirements of the Local Government Board satisfied in the future.

MANCHESTER: *Overhead Wires.*—There is the possibility of conflict between the Post Office authorities and the Corporation on the question of erecting further poles for telegraph purposes. The Highways Committee have withheld their consent to the proposals of the Post Office, and the matter will be discussed by the Corporation on consideration of the Highway Committee's report. In connection with the same controversy, the Watch Committee have given permission for the attachment of overhead wires to the tramway posts for the Gamewell system of fire-alarms, a course of action which the Highways Committee somewhat resents, as an interference with their functions. As a consequence, an application for consent to certain underground work connected with the fire-alarm system has been rejected by the Highways Committee. Advocates of the attitude of the Highways Committee refer to the fact that as long as 14 years ago the Corporation decided not to allow the erection of any further overhead wires, and an agreement was then made with the National Telephone Co. to place all further wires underground.

MIDDLESBROUGH: *The Power Companies Bill.*—The Bill which has been deposited by the County of Durham Electric Supply Co. for next session was discussed by the Corporation last week. This Bill provides for working agreements between the various electric power companies on the north-east coast, and the Chairman of the Electric Lighting Committee expressed the opinion that the effect of the Bill would be in the direction of cheapening than increasing the cost of supply. No resolution was passed on the subject.

MORECAMBE: *Tramway Arbitration.*—The evidence and speeches in the arbitration concerning the purchase of the horse tramways of the Morecambe Tramways Co. by the Corporation have now been concluded, and the arbitrator's decision will be announced in due course.

OLDHAM: *Electric Supply.*—Mr. S. W. Newington, the electrical engineer, states that since March last there has been an increase in private lighting and power supply equal to 30 per cent., the units sold being 1,149,000, against 887,000 during the corresponding period of last year. In traction there has been an increase of about 11 per cent. during the same period.

PRESTON: *Proposed Purchase of Supply Co.*—At a meeting of the Preston Trades Council last week a resolution was passed expressing the opinion that the time had arrived when the undertaking of the National Electric Supply Co. should be acquired by the Corporation.

RHONDDA: *Tramwaymen's Grievances.*—Considerable dissatisfaction exists amongst the employees upon the Rhondda tramways, and at a meeting held recently the determination was expressed to fight the company. One of the men's grievances is that conductors and drivers were promised an increase of a halfpenny per hour after six months' service, but neither of these increases has been granted, although the period agreed has expired. On the other hand, the company states that the agitation has been fostered by one individual who had been discharged, and if any of the other employees were discontented they could be paid off if they chose, as there were any number of qualified drivers ready to take their places.

ROTHERHAM: *Supply in Adjacent Districts.*—The Electric Light Committee have considered the report by the electrical engineer for supplying districts adjacent to the borough with electricity, and have requested a further report dealing with a particular district.

Thermit Rail Welding.—The Tramways Committee have investigated the Thermit welding system, tests of which have recently been carried out by the Borough Engineer. For the present, however, the use of Dicker fish-plates and inverted anchors will be continued.

SALFORD: *Electricity Committee Summoned.*—The Salford Electricity Committee have been summoned by the Public Health Department for allowing black smoke to be emitted from the chimney of the Frederick Road Electricity Works. The Deputy Town Clerk supported the summons, and it seems that the summons was taken out at the instance of several manufacturing neighbours, who complained that, whilst they were being summoned for similar offences, the Electricity Committee were being allowed to emit smoke without being proceeded against. Mr. V. A. H. McCowen, the Borough Electrical Engineer, stated that it was due to exceptional circumstances that the offences complained of had been committed, it being due on one occasion to the testing of coal, and on another to the breakdown of one of the economisers. A fine of five shillings was imposed, with an order to abate the nuisance. The magistrates complimented the Corporation upon summoning one of its own departments.

SHEFFIELD: *The Trackless Trolley System.*—Some suggestion is made in Sheffield that a deputation should be sent to Austria to inspect the trackless trolley system in operation there. The critics of the Corporation, however, urge that as there are no other tramways which can be constructed in Sheffield in the near future, it would be policy to go slowly in the matter and profit by the experience of other cities.

SOUTH SHIELDS: *Energy for Tramways.*—The Corporation has adopted the recommendation of the Electricity Committee, set forth on page 17 of our last issue, refusing to make a reduction in the price charged to the Tramways Committee for electrical energy.

SWANSEA: *Electric Lighting Extensions Abandoned.*—Mr. C. A. L. Prussman, the electrical engineer, has advised the Electric Lighting Committee not to extend their mains to the Townhill Estate, which is now being developed in connection with the Cottage Exhibition, as there will not be any prospect of a profit. The cost is put at £2,500.

WALLASEY: *Tramway Proposals Defeated.*—At the statutory ratepayers' meeting last week the proposal of the Council for tramway extensions was defeated on a vote, and a poll of the ratepayers is to be taken.

WALSALL: *Chairman of Electricity Committee.*—Alderman W. Brownhill has resigned the chairmanship of the Electricity Committee. A special meeting of the committee is to be held shortly, and it is said that Councillor Stead, the present vice-chairman of the committee, will be elected as Alderman Brownhill's successor.

WEST HAM: *Local Government Board Inquiry.*—In regard to the adjourned Local Government Board inquiry, the details of the estimate have been revised, although the total of the application (£51,600) for the proposed loan remains at the same figure.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

DERBY.—A water-softener for the old power station is to be procured at a cost of £300. An application is to be made to the Local Government Board for permission to purchase the water-softener out of the sum granted for the construction of the new works, which has not yet been expended.

HEREFORD.—The Electric Lighting Committee recommend an application to the Local Government Board for sanction to a loan of £5,700 for the provision of water-cooling and induced draught plant and cable extensions during the next three years.

MIDDLESBROUGH.—A booster is to be installed at the electricity works at an estimated cost of £220.

SWINDON.—The Electricity and Tramways Committee, having considered the proposals to extend the plant at the generating station, have recommended that the matter should be postponed until September, but that in the meantime the Electrical Engineer should report as to the additional plant required immediately.

Miscellaneous

BRAY.—An expenditure of £300 upon transformers has been authorised by the Council.

HUNGARY.—The *Board of Trade Journal* quotes a foreign exchange to the effect that the authorities of the town of Kiskunfélegyháza (Hungary), who had decided to place the electric lighting of the town in the hands of the Hungarian branch of the Siemens-Schuckertwerke Co. in Budapest, has decided at the last moment to carry out the work on their own account, and to order the necessary machinery themselves.

LIVERPOOL.—The sum of £1.204 is to be expended in providing telephone communication for police and fire purposes.

PLYMOUTH.—Tenders are invited by the Corporation for the supply of the following stores during the year ending March 31st, 1910:—Arc lamp carbons, electricity meters, transformers, cables (paper insulated), lubricating oils, &c., engine waste, &c. Particulars from the Borough Electric Engineer, and tenders by January 30th.

Digitized by Google

SPAIN.—Tenders may be presented until noon on January 20th, says the *Board of Trade Journal*, at the "Gobierno Civil" of Orense, or at the "Registro de la Dirección general de Telégrafos," Madrid, for the construction and working of an urban telephone system in Orense. The contract will be adjudicated at the above-named "Dirección general," at 11 a.m. on January 25th. A deposit of 2,000 pesetas (about £71) will be required to qualify any tender. Local representation is necessary. A copy of the conditions and of the form of tender may be seen by British contractors on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

SWITZERLAND.—The *Board of Trade Journal*, quoting from a Swiss journal, states that a concession has been accorded to MM. Charles Wolf, engineer, of Nidau, Ed. Rufer, notary, of Bienne, J. Laubscher, deputy, of Täuffelen, and Dr. R. Hagen, of Anet, for the construction and working of an electric railway of standard gauge from Bienne to Anet *via* Täuffelen. Similar concessions have been granted (1) to M. Balestra, advocate, of Lugano, for an electric railway from Lugano to Ponte Cremenaga, *via* Bioggio, Sorengo, Agno, and Ponte Tresa; (2) to M. C. Pfaltz, engineer, of Chiasso, for an electric railway covering part of the route between Chiasso and Muggio.

URUGUAY.—The *Board of Trade Journal* states that a decree has been published, authorising the Junta Economico-Administrativa of Rocha to enter into a contract with Mr. Federico Ribas for the lighting of the town of Rocha by electricity. The contract is for a term of twenty years.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

S.W.—Additions to Wimbledon College, Edge Hill, Wimbledon. Architect, F. A. Walters, 37 Old Queen Street, S.W.

Additions to Westminster School. A. Hersell Tiltman, Raymonds' Buildings, W.C.

S.E.—Proposed erection of buildings for Doulton & Co., Ferry Street, Albert Embankment. Surveyors, Buckland & Garrard, 8 Frederick's Place, E.C.

Branch library, New Cross Road, Deptford (£4,500). Architect, Borough Council.

W.—Rebuilding 27 and 28 Oxford Street for Parkins & Gotto, stationers.

The Kensington Guardians have instructed the Workhouse Committee to obtain estimates for the electric lighting.

Rebuilding 163 Oxford Street and 35, 36, and 37 Poland Street. Phillips, Phillips & Co., agents, 6 Newman Street, W.

Mansions in Park Street and Upper Grosvenor Street, Mayfair. Architect, W. D. Caröe, 3 Great College Street, S.W. Builder, Higgs & Hill, Ltd., South Lambeth Road, S.W.

School for boys (450 places), Kilburn Park Road, Paddington. Rev. P. H. Leary, vicar, St. Augustine's, Kilburn Park Road.

PROVINCES.

ABERDEEN.—Additions and alterations to the City Hospital (£12,000). J. Rust, City Architect, Aberdeen.

ARBROATH.—Reconstruction of the railway station (£50,000). Secretary of the Caledonian and North British Railway Companies.

BURY.—Municipal Secondary School (£13,000). Architect, J. T. Halliday, Stockport.

COATBRIDGE, N.B.—Messrs. Arnott's new premises (£10,000).

DONCASTER.—Block of shops and offices. Architect, E. Wilburn, St. George's Gate, Doncaster.

DURHAM.—School, Mount Pleasant. Architect, W. Rushworth, Shire Hall, Durham.

County school, Tudhouse Grange. Architect, W. Rushworth, Shire Hall, Durham.

EDINBURGH.—Police station, McLeod Street. Architect, J. A. Wilkinson, City Chambers.

GLASGOW.—Factory, Ladywell Street. Architects, Miller & Black, 58 Renfield Street.

GLOUCESTER.—Extensions to Shire Hall. Town Clerk, G. Sheffield Blakeway.

ILFRACOMBE.—New Post Office. H.M. Office of Works, Storey's Gate, London, S.W.

JARROW.—Public baths (£4,000). Architect, J. Morton, 50 King Street, South Shields.

LEICESTER.—Public hall, Regent Road (£15,000). S. P. Pick, Borough Surveyor.

LIVERPOOL.—Workshops for the blind, Cornwallis Street. Architects, Holt & Glover, 42A Imperial Buildings, 20 Exchange Street, East, Liverpool.

MOTHERWELL, N.B.—Depôt buildings. Borough Surveyor, Town Hall.

OLDBURY (WORCS.).—Schools at Abbey Road (£9,485). T. H. Shipton, Surveyor to Urban District Council.

SOUTH SHIELDS.—Bank premises, North-Eastern Banking Co. Architect, J. Morton, S. Shields.

STAPLE HILL (BRISTOL).—Council school at Soundwell Road. Architect, R. S. Phillips, Midland Bank Chambers, The Cross, Gloucester.

WALLSEND-ON-TYNE.—Concert hall. Architect, E. Cratney, High Street, Wallsend.

WATFORD.—Adaptation of old grammar school for higher elementary school (£1,000). A. R. S. Hallidie, Secretary to Herts. Education Committee, Hertford.

TENDERS RECEIVED AND ACCEPTED

ACCRINGTON.—The Council has accepted the tender of Messrs. E. Wood & Co., of Salford, for the steel roof and girder work required in connection with the extension at the tramway depot.

AFRICA.—The *Financial News* states that, according to a telegram from Berlin, the Siemens-Schuckert works, together with the Allgemeine Elektricitäts-Gesellschaft, have received important orders for electrical materials intended for the German colonies in South-West Africa.

AUSTRALIA.—The New South Wales Postmaster-General's Department has, says the *Australian Mining Standard*, accepted the tender of Messrs. Lawrence & Hanson, of Sydney, for 15 switchboards for private branch exchanges, for common battery working, one line to main exchanges, three lines to sub-stations, one cord circuit for exchange lines, one cord circuit for sub-stations, at £9 2s. 3d. per switchboard; 15 switchboards, for private branch exchanges, for common battery working, two lines to main exchange, five lines to sub-stations, two cord circuits for exchange lines, two cord circuits for sub-stations, at £13 2s. 6d. per switchboard; three switchboards, for private branch exchanges, for common battery working, three lines to main exchange, ten lines to sub-stations, three cord circuits for exchange lines, three cord circuits for sub-stations, at £18 1s. 9d. per switchboard. Contractors to supply local bell contacts at an additional cost of 1s. 6d. per line.

BELGIUM.—The following tenders have been received for the overhead electric equipment and electrical connections on La Louvière and Binche Railway, for the Société Nationale des Chemins de Fer Vicinaux, Brussels:—Société de l'Electricité Industrielle, Liége, £3,240; La Compagnie Générale d'Electricité, Paris, £3,280; La Compagnie Belge d'Electricité Siemens-Schuckert, Brussels, £4,483.

CARDIFF.—The tender of Messrs. Pearson & Huggins, of Bristol, for uniforms for the tramway employees, at £577 for drivers and conductors, and £28 10s. for inspectors, has been accepted.

CHESTER.—The tender of the British Thomson-Houston Co., Ltd., for the supply of incandescent lamps required by the electricity department during 1909, has been accepted.

DUNDEE.—The following tenders have been accepted in connection with the Lochee sub-station:—Mr. James Binny, mason's work; Mr. Thomas Russell, steel work; Messrs. Comb & Sons, joiner's work; Messrs. P. Anderson & Sons, plumber's work; Mr. M. Lawless, plasterer's work; Mr. Charles Brand, slater's work; British Luxfer Co., patent glazing.

LONDON: *Metropolitan Asylums Board.*—An order has been placed with the Electric Vehicle Co. for two 5 cwt. electric vans.

Greenwich.—The Council have accepted the tender of G. H. Beaver to supply and fix Osram lamps in the Council Chamber and in the large hall at the Borough Hall at 4s. 3d. per lamp.

Hackney.—The Council have accepted the tender of the Rees Roturbo Manufacturing Co., Ltd., at £54, for an electrically-driven pump in connection with the separation of oil from the air-pump discharge water at the electricity works.

Stepney.—The Borough Council have placed another order with Messrs. Cory Bros. & Co., Ltd., for the delivery, as required, of Pentre washed small coal at 18s. per ton, a reduction of 5d. per ton on the previous order of 1,000 tons. The contract is up to July next.

MANCHESTER.—The following tenders have been accepted by the Tramways Committee:—Brush Electrical Engineering Co., 38 pairs maximum traction tramway trucks; H. Wallwork & Co., Manchester, car resistances; W. Scott, Limited, Leeds, 500 tons of steel girder tramway rails.

MIDDLESBROUGH.—An order has been placed with Messrs. Crompton & Co., Ltd., for street posts and arc lamps at £647 10s.

SOUTH AFRICA.—The acceptance by the Uitenhage Town Council of the offer of the General Electric Co., of London, to supply 27,000 candle-power for the streets at £825 per annum, the plant to be taken over by the Council within ten years,

Digitized by Google

has, says *South Africa*, now been ratified by the ratepayers in public meeting assembled. The price at which the Council takes over the plant is to be fixed by arbitration.

WALSALL.—The tramway cars are to be equipped with the British Thomson-Houston electro-mechanical track brakes at a cost of £33 per car set, exclusive of the cost of fixing, which is to be done by the Council staff. The right to advertise on the tramcars has been let to Messrs. Griffiths & Millington, Ltd., London, for five years.

WEST HAM.—The following tenders have been received for repairs, extensions, and testing of the electric lighting installation at The Grange, Harold Wood :—J. T. Halsey (accepted), £40 14s. 6d.; Vulcan Electric Co., £54 17s.; W. Simmons, £69 10s.; Laing, Wharton & Cunnington, £78.

APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. P. J. Pringle, the electrical engineer and tramways manager at Burton-on-Trent, has been increased by £25 per annum.

The Hackney Borough Council are inviting applications for the post of electrical draughtsman at a commencing salary of £150 per annum, rising by annual increments of £12 10s. to £175 per annum.

The salary of the Rochdale tramways manager, Mr. Moffet, has been increased by £50 per annum, with two further yearly increases of £25, bringing the salary up to a maximum of £400.

Mr. D. M. Kinghorn, Electrical Engineer to the Metropolitan Borough of Southwark, has resigned his appointment.

The Swansea Harbour Trust received no fewer than 449 applications for the position of Electrical Engineer. A short list of seven has been prepared, but it is thought possible that Mr. Hopkin Morgan, Electrical Engineer to the Port Talbot Co., is the likely selection.

The late Prof. W. E. Ayrton's will has been proved at £43,590.

The Rawtenstall Council received 137 applications for the position of Borough Electrical Engineer. The short list was reduced to four, as follows :—Mr. C. L. E. Stewart, Rochdale; Mr. A. W. Clegg, Deputy Electrical Engineer, Accrington; Mr. H. Lassey-Bull, Wigan; and Mr. J. Boyce, Darwin, from which a final selection will be made. The salary attached to the post is £200 per annum.

Mr. K. A. E. Bashell, chief correspondence clerk, West Ham electricity undertaking, is to have his salary raised from £125 to £140 per annum, with a further increase to £150 at the expiration of 12 months.

Mr. A. E. Ford has been appointed manager of the Adelaide electric tramways. Mr. Ford has been manager of the Bendigo (V.) electric supply and tramways undertaking.

Mr. G. L. Just, of the Sydney office of the Edison & Swan United Electric Light Co., has been appointed manager to the company at Melbourne.

NEW PUBLICATIONS

"The Theory of Electric Cables and Networks." By Alexander Russell. (London : Archibald Constable & Co.). 8s.

"The Internal Combustion Engine." By H. E. Wimperis. (London : Archibald Constable & Co.) Price 6s.

Proceedings of the American Institute of Electrical Engineers, January, 1909. (New York : The Institute.) Price $1.

Proceedings of the South Wales Institute of Engineers, December, 1908, and January, 1909. (Cardiff : The Institute.)

The "G.B." Surface-Contact System in London.—The decision of the London County Council to modify the track and car equipments on the Bow road-surface contact tramway route has, says *The Times Engineering Supplement*, resulted in a contract being entered into with the "G.B." Co. t ocarry out the necessary modifications over a mile of line, and to equip one car for experimental working. The midifications of the track work which are now being carried out are of the simplest character, the most important operation being the taking up, examination, cleaning, and replacement of the studs. Nothing is at present being attempted in regard to improving the track equipment at junctions and crossings; that work, which is necessarily of a more expensive character, being left to await the result of the present experiment. The main work which the "G.B." Co. have undertaken is in connection with the car equipment, which was originally carried out by the London County Council. The chief alterations being made are that the section of the core bars has been increased so that they are not magnetically saturated, the metal parts are being properly covered so as to protect them from the effect of picking up scrap, and the general shape of the magnet is being altered so as to give ample clearance between parts of the track and itself. It is hoped that the whole of the work will be completed next month, and that experimental runs, which will then take place, will demonstrate that the system can be safely employed even under the traffic conditions which prevail in the metropolis.

MISCELLANEOUS CITY NOTES

DUBLIN UNITED TRAMWAYS CO.—The directors recommend a dividend of 6 per cent. per annum (6s. per share), free of income tax, on the ordinary shares for the half-year to December 31st. The sum of £13,251 has been charged against relaying the track in Blackrock, carrying forward £8,149.

CHILI TELEPHONE CO.—The directors have declared an interim dividend of 3s. per share, free of tax, for the half-year to December 31st, payable on January 15th.

CITY & SOUTH LONDON RAILWAY CO.—The accounts for the half-year to December 31st, 1908, show a balance, after providing for debenture interest, dividend on the 5 per cent. preference stocks 1891, 1896, 1901, and 1903, and the transfer to the renewal fund of £1,500, sufficient to allow the payment of a dividend on the consolidated ordinary stock at the rate of 1½ per cent. per annum, carrying forward a balance of £954. The dividend for the corresponding period last year was 1¾ per cent. per annum, carrying forward a balance of £1,119.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £65 10s. to £66 per ton (last week, £66 5s. to £66 15s. per ton).

A SILVERTOWN "MARATHON."—On Saturday last a 10½ mile road race was contested by 37 employees of the India Rubber, Gutta Percha & Telegraph Works Co., Ltd., Silvertown, E. This local "Marathon" created tremendous interest, thousands of spectators lining the route, which was a circular one, commencing and finishing at the Eagle Hotel, Snaresbrook. G. Peters won the race in 63 minutes, excellent time considering the heavy "going."

NEW COMPANIES

BONNINGTON ELECTRIC LAUNDRY CO.—This company was registered in Edinburgh on December 31st, with a capital of £500 in £1 shares, to carry on the business of an electric and general laundry at Lanark and elsewhere. The number of directors is not to be more than three. D. Martin is the first. Qualification 100 shares. Remuneration not to exceed £100 per annum.

GUARANTEED PUBLIC WORKS CO.—This company was registered on December 23rd, with a capital of £1,000 in £1 shares, to seek and obtain contracts, orders, or concessions for railways, harbours, canals, tramways, means of transport, sewers, buildings, electric lighting, power, and general engineering works and construction in any part of the world having Government, municipal, or other guarantees or prospects of profit or other revenue, or at the discretion of the directors to engage any business, with or without guarantees, which appears likely to be profitable. Registered office, 16 Essex Street, Strand, W.C.

MIDLAND ELECTRIC MANUFACTURING CO.—This company has just been registered with a capital of £3,000 in £1 shares, to take over the business of manufacturers of electrical appliances and fittings carried on by G. T. Thornhill, W. L. Barber, and F. W. Abbott, at 140 Conybere Street, Birmingham, as the Midland Electric Manufacturing Co. The subscribers are :—W. L. Barber, Acocks Green, Worcestershire, electrical engineer; F. W. Abbott, Kenelm Road, Small Heath, Birmingham, electrical engineer. Private company. The first directors are G. T. Thornhill, W. L. Barber, and F. W. Abbott. Qualification 200 shares. Registered office, 140 Conybere Street, Birmingham.

WEST OF SCOTLAND TRADING CO.—This company was registered in Edinburgh on January 2nd, with a capital of £2,500 in £1 shares, to carry on the business of general merchants, electric and mechanical engineers, iron and brass founders, lighting contractors, iron, steel and metal merchants, plant and machinery brokers, &c. The number of directors is not to be less than two nor more than five; the first are not named. Qualification, 100 shares. Remuneration, £50 each per annum (chairman £75). Registered office, 140 W. George Street, Glasgow.

WALLACH BROTHERS.—This company was registered on December 23rd, with a capital of £15,000 in £1 shares (5,000 pref.), to take over the business carried on by J. Wallach and L. C. Wallach, as "Wallach Brothers," and to carry on the business of asbestos and rubber manufacturers and dealers, engineers, mill furnishers, chemical merchants, machinery dealers, manufacturers, and contractors, dealers in proprietary articles, and electrical, chemical, scientific, and photographic apparatus and materials, &c. Private company. The number of directors is not to be less than two nor more than five; the governing directors are J. Wallach and L. C. Wallach, each of whom may retain office while holding one-third of the issued shares. Registered by Robinson, Stannard & Bosanquet, 19 Eastcheap, E.C.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 7th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

28,044/07, **Mounting the Commutators of Turbo-generators.** A. TYSON-WOLFF (*H. L. Tyson Wolff*). This specification describes a method of fixing the commutators to the shafts of high-speed machines, so that expansion of the former can take place without a distortion of the shaft or a loosening of the means of fixing. A sleeve of a slightly larger diameter than that of the shaft, is tapped internally at one end, so as to screw over a threaded boss on the shaft. To fix this end, a ring is shrunk over it, and a screw passed through ring and sleeve into the shaft. At the other end, the sleeve is free to move longitudinally, but is adjusted radially by means of screws bearing upon hardened steel keys. Oblique slots are cut in the sleeve, to give it elasticity in a longitudinal direction. The commutator is supported on coned rings fixed over each end of the sleeve, and is held together by two or more rings shrunk over it. The invention is not limited to commutators, but can be applied to the mounting of any structure on a shaft. Four claims, one figure.

28,138/07, **High Efficiency Tungsten Filament Lamps.** ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT. The fusing point of a tungsten filament is reached when the specific consumption or "efficiency" is about 0·33 watts per candle. If the filament is heated to a temperature corresponding to a consumption of about 0·7 to 0·8 watts per candle, the resistance of the filament gradually increases, as it softens and sinters together, becoming thicker and shorter. This allows the current to increase, and the filament is soon burnt out; serious blackening of the lamp does not occur, however. According to the present invention, it is proposed to insert a resistance with a positive temperature coefficient—such as an iron coil in a bulb filled with hydrogen—in series with a tungsten filament to enable it to be run at an "efficiency" of 0·7 to 0·8 watts per candle, without unreasonably shortening the life of the lamp. Thus a filament taking 0·6 amp. at 140 volts at this efficiency, could be run off an 150-volt circuit, the iron resistance absorbing 10 volts. Variations in the supply pressure will be compensated for, and the reduction in the resistance of the filament retarded. The resistance could be placed in the lamp itself. By running the filaments at such a high efficiency, the length of filament for a given pressure is considerably shortened, and thus lamps can be constructed for comparatively high pressures. Three claims.

4,956/08, **Manufacture of Metal Filaments.** F. J. PLANCHON. An improved process for preparing a homogeneous plastic compound of tungsten for squirting into lamp filaments is described in this specification. A carbo-hydrate, such as gum-arabic, starch, and cellulose, is dissolved, and the aqueous or alkaline solution obtained is mixed with an alkaline solution of tungstic acid. The mixture is then poured into dilute hydrochloric acid, and a precipitate, which is a chemical compound of tungstic acid and the carbo-hydrate, is obtained. The precipitate is washed and made into a paste with water, after which it is ready for the usual squirting process. Two claims.

11,517/08, **Constant Voltage Interpole Generator.** SIEMENS-SCHUCKERTWERKE GES. According to this invention, the main poles of a continuous-current interpole generator are partly or entirely excited by means of the current obtained from double brushes in the commutating zone. With such brushes, which are generally connected together through a resistance, the current which flows between them is dependent upon the difference between the armature and interpole ampere-turns, and the E.M.F. of self-induction of the armature coils between the two halves of the brush. If the speed decreases, and consequently the armature current (owing to the decreased pressure), the current between the brush-halves will increase considerably if the interpoles are provided with separate excitation, and the main poles will thus be further excited. This affords a means of obtaining a constant pressure with variable speed. Furthermore, the generated E.M.F. is independent of the direction of rotation, as, if the machine reverses, the voltage between the brush-halves also reverses. Such a generator would be suitable for coupling to a wind motor. Three claims, three figures.

16,766/08, **Electromagnetic Clutch.** SIEMENS BROTHERS DYNAMO WORKS, LTD. (*Siemens-Schuckertwerke Ges.*). The object of the clutch described in this specification is to enable two shafts to be coupled together electromagnetically, without it being necessary to displace the halves of the coupling axially on the shaft. The electromagnet is mounted stationary outside the coupling, and the two halves of the coupling are formed by annular magnet-armatures, each of which is fixed to the hub of its shaft by flexible means, such as a diaphragm disc or springs. When the electromagnet is excited, the gripping surfaces of the armatures are brought into contact, and the shafts are coupled together. Four claims, six figures.

16,797/08, **Prevention of Deposit in the Globes of Arc Lamps.** T. J. RENSING. The ash from arc lamp carbons, and particularly that from the chemically impregnated carbons used in flame arc lamps, is frequently deposited on the sides of the globe. To prevent this in the case of lamps for outdoor use, the present invention provides for the use of an inverted cowl at the bottom of the globe, to ensure a good upward current of air round the inside of the globe. The air is carried round an ash plate fixed in the bottom of the globe. Two claims, four figures.

17,535/08, **Protection of the Economisers of Flame Arc Lamps.** ALLGEMEINE ELEKTRICITÄTS GES. This specification describes an improved method of protecting the economiser of a lamp with converging carbons, when the carbons burn down so that the arc approaches the roof of the economiser. A magnet for extinguishing the arc when the latter approaches it has not proved altogether suitable for this purpose. According to this invention the feeding of the carbons is prevented by means of a stop when their length has reached a predetermined minimum, and consequently the arc lengthens out and is finally extinguished owing to the rise in pressure. Three claims, one figure.

17,730/08, **Alternating-current Integrating Meter.** R. KENNEDY. This invention relates to alternating-current meters of the induction motor pattern, and provides means whereby the relative torque of the electromagnets on the rotating disc can be easily adjusted. The large shunt-wound magnet, which is fixed, is provided with as small an air-gap as possible, in order that it may be sufficiently inductive to cause the necessary difference in phase between the two fluxes. On either side of this magnet, which is placed tangentially to the disc, are placed small series magnets with their limbs radial to the disc. The two latter are adjustable in relation to the shunt magnet. It is important that the combined sectional area of the limbs of the series magnet should not exceed one-fifth of the sectional area of the shunt magnet. Alternately the system may consist of two large shunt magnets and one small series magnet, the two former being adjustable in that case. Five claims, six figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WEIDINGER & KAHN [Insulating material] 28,117/07; BRITISH INSULATED & HELSBY CABLES, LTD., and SAUNDERSON [Jointing of wires] 28,334/07; BOULT (*Woodbridge*) [Distribution] 345/08; BRAY and BRAY, MARKHAM & REISS, LTD. [Insulated conductors] 8,962/08.

Dynamos and Motors: MAVOR, & MAVOR & COULSON, LTD. [Control of induction motors] 28,040/07.

Electrometallurgy and Electrochemistry: COWPER-COLES [Galvanising and tinning apparatus] 28,636/07; LÉVY [Removing metallic coatings from metallic surfaces] 13,666/08.

Ignition, Electric: BRITISH THOMSON-HOUSTON CO. & HOPPS, 3,985/08; LEWIS & BRIGGS, 8,940/08; MULLER, 12,894/08.

Instruments and Meters: MOSELEY, 28,080/07; SIEMENS BROS. & Co. (*Siemens & Halske Akt.-Ges.*) [Photometric screens] 19,344/08; PATTON [Apparatus for testing armature windings] 20,578/08.

Switches, Fuses, and Fittings: ESCARÉ, ESCARÉ & DAMEY [Candle-lamp fittings] 104/08; GLOVER [Street lantern] 2,607/08; ROTH [Switch lamp-holders] 14,080/08; WEISSE [Fuses] 15,330/08; DORMAN, SMITH & BAGGS [Lamp-holders] 21,332/08.

Telephony and Telegraphy: MOSELEY [Telephone transmitters] 28,081/07; CHADBURN'S SHIP TELEGRAPH CO. & GRANT [Ship's telegraph apparatus] 5,172/08; DE BERNOCHI [Transmission of pictures] 11,446/08; KINGSBURY (*Western Electric Co.*) [Switching apparatus] 21,075/08; EISENSTEIN [Wireless Telegraphy] 25,029/08.

Traction: BOIRAULT [Brakes] 28,620/08; SHEPHERD and ULLERY [Trolley Poles] 153/08; JOHNSON [Electrically operated points and signals] 2,085/08; SAYER [Control of electric vehicles] 10,006/08; HENSHAW and SWINDELLS [Control of trolley poles] 10,552/08; S. P. (SUCHOSTAWER PATENTS) SYNDICATE and SAYERS [Surface-contact traction system] 21,628/08.

Miscellaneous: DAWSON and BUCKHAM [Control of the sighting of guns] 21,414/07; RAPID MAGNETTING MACHINE CO., THOMPSON, and DAVIES [Magnetic separating machines] 28,014/07 and 28,015/07; STONE [Electric pianos] 18,086/08; SIEMENS BROS. DYNAMO WORKS, LTD., and KLOSS [Flexible shaft-coupling] 18,221/08; BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Friction clutches] 18,369/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

SOC. ANON. MONT CARBON [Magneto ignition] 24,737/08; FESSENDEN [Wireless telegraphy] 25,305/08; MAYER [Trolley-wire suspension] 26,485/08; SIEMENS-SCHUCKERTWERKE GES. [A.C. meters] 27,343/08; WALLACE and REYNAUD [Rubber substitute] 27,688/08; ALEXANDERSON [Commutator motor] 28,189/08; ALLGEMEINE ELEKTRICITÄTS GES. [Motor-starter] 28,192/08.

DEATH FROM ELECTRIC SHOCK AT LOT'S ROAD POWER STATION

WE reported, briefly, in our last issue the circumstances of the death of a labourer named W. J. Reader, at the Lot's Road generating station of the Underground Electric Railways Co. of London, on December 28th It appears that the deceased had been instructed to paint and clean the inside of one of the Babcock & Wilcox boilers there, and as he was a longer time than usual he was searched for, when it was discovered that he was dead. At the opening of the inquest on January 1st, Dr. Ross, of Cremorne Road, S.W., expressed the view that the man met his death from electric shock. The *post-mortem* examination revealed a charred mark under the right elbow about 1½ in. long, and from appearances the man had fainted whilst inside the boiler, as when the body was removed it was wet with perspiration. In view of the fact that the hand lamp by the aid of which the man had been working was found broken inside the boiler, the Coroner decided to call expert evidence, and the inquest was accordingly adjourned, the Home Office meanwhile being communicated with.

The adjourned inquest was held on Monday, when Mr. G. Scott Ram, Electrical Inspector of Factories to the Home Office, and Dr. T. M. Legge, Medical Inspector to the Home Office, were present and gave evidence. At the previous inquiry, some discussion took place as to the fumes given off by a compound which was being used by the deceased for painting the inside of the boiler and which was, as a matter of fact, being used in the station for the first time. This particular material was "Apexior" compound, manufactured by Messrs. J. Dampney & Co., of Cardiff, and although its exact contents are a trade secret, it may be said that it contains a volatile spirit of the nature of benzine or naphtha. The compound is said to be non-explosive, with a flash point of over 100° F., and instructions are issued that no naked lights should be used. Another instruction issued by the makers, in connection with the application of this compound to the interior of boilers is that the boiler should be allowed to get cold before using and opened out as much as possible to allow air to get to the men painting. On the day of the accident when, as stated above, the paint was being used for the first time, no extra precautions were taken for ventilating the boiler for getting rid of the fumes. The manholes and the cock on the top were open, as usual, but none of the headers. The Coroner was inclined to place some importance upon this, but as Mr. J. B. Dampney, managing director of Messrs. J. Dampney & Co., the makers of the compound, considered this ample ventilation, the boiler being cold, and as, moreover, since the accident, three other boilers have been treated internally with the same compound with precisely the same amount of ventilation, this possible cause of death was not pursued. In fact, the foreman stated that the smell from the paint was a pleasant one, something like that of Sanitas disinfectant. As this compound is largely used in electric power stations, however, it is interesting to note that experiments have been carried out in the Government Laboratory as to the effect of the fumes upon animals. Dr. Thorpe, the Government Analyst, has analysed a sample and found that it contains a volatile hydro-carbon, which, in a confined space, would produce faintness and eventually insensibility. This was discovered by placing two mice in separate glass jars. In one of them a little of the paint was placed, and in the other none, air being admitted through the perforated zinc at the tops. At the end of seven minutes, the mouse in the jar containing the paint became disturbed, in 34 minutes it was unconscious, and in a few hours it died. Dr. Thorpe also found that the volatility of the compound was very great.

Consideration was next given to the portable electric lamp with which deceased was working. Mr. G. S. Ram, H.M. Electrical Inspector of Factories, stated that generally it was no better and no worse than the majority of hand lamps in use nowadays. There had, he said, been previous fatal accidents from the use of hand lamps and he had for some years been hammering away at the subject in his annual reports. It was only just now that manufacturers had begun to try to make better lamps. The particular lamp, it may be said, was of American make, with an Edison screw socket lamp, and was the first of its kind to come under the notice of Mr. Ram. When recovered from the boiler, the flexible had been torn away from the connections in the handle, but whether this had been done by the deceased or in the act of pulling the lamp out of the boiler after the accident was not clear. Had this been done accidentally by the man himself it was possible for the wires to have made some of the metal at the end of the wooden handle alive, and for him to receive a shock. Again, in this make of portable lamp there is a ring of metal, surrounded by porcelain, forming part of the circuit. This porcelain, however, had a considerable crack in it, but no portion of this crack appeared to be recent, as it was in a very dirty condition. A big hole was also burned on one side of the cap, but as the fuse in the circuit was found intact after the accident, Mr. Ram expressed the opinion that it could not have been caused on the day of the accident, as the current would certainly have been sufficient to have blown the fuse. The general conclusion come to by Mr. Ram was that the man received a shock from the lamp, and this was concurred in both by Dr. Legge and Dr. Ross. The latter gentleman said that from his examination of the deceased it was quite clear that he had, from some cause, fainted whilst inside the boiler and fallen on the lamp, smashing it, the shock proving fatal owing to his weakened physical condition. The cause of the fainting he was unable to state definitely, but it was conceivable that the man had been overcome by the fumes from the paint. On the other hand, the fumes might not have been a factor in the case at all. The temperature inside the boiler just after the accident was 80 degrees, which was, in fact, less than outside. Dr. Ross was quite emphatic that death was not due to asphyxia, and equally so that the burning on the elbow had occurred before death. Mr. J. W. Towle, Resident Engineer at Lot's Road Power Station, said that the voltage of the lamp was 220, and that it was the duty of the foreman to have seen that it was in good order, as there was an electrical staff to attend to these things.

The Coroner's summing up was in favour of there having been sufficient ventilation in the boiler for preventing the fumes having a fatal effect in themselves, and the jury returned a verdict that death was due to electric shock, adding that the portable electric lamps in use at Lot's Road are insufficiently protected. The jury further expressed the opinion that men working under such conditions as the deceased at the time of the accident should be visited at frequent intervals.

PRODUCTION OF NITRIC ACID BY THE ELECTRIC DISCHARGE

SEVERAL speakers in the recent discussion on Messrs. Cramp and Hoyle's Paper on the electric discharge and the production of nitrogen, read in December before the Institution of Electrical Engineers, mentioned the process employed for the "fixation" of atmospheric nitrogen of the Badische Anilin und Soda Fabrik, but neither the authors of the Paper nor the speakers in the discussion were able or willing to give any information as to the nature of the process. The following description of the method employed, which is taken from the *Electrical Review and Western Electrician* (Chicago), will therefore be of interest:—

Almost the reverse of the older form of electric arc employed in the Birkeland-Eyde process of nitrogen extraction from the air, in which a high-tension, alternating-current flame is blown into a veritable disc transversely to a direct-current magnetic field, is the method used by the Badische Anilin und Soda Fabrik, which has a working agreement with the Birkeland-Eyde Company. Long, thread-like arcs are employed to oxidise the nitrogen of the air. The air is blown tangentially so as to circulate spirally around the quietly-burning arc. In some examples of this apparatus recently exhibited the tubes were of glass, coated on the inner periphery by a wire spiral, which was in metallic contact with a knob at the top of the tube. At the bottom of the tube the wire spiral is only separated by a short distance from the other electrode, which is placed in the axis of the tube. When a 3,000-volt supply is applied between the two electrodes a spark jumps across, and the arc travels rapidly up the tube. If, now, air is forced in at the bottom through a number of symmetrically-placed tangential nozzles, the arc burns quietly in the axis of the tube without touching the sides, and absorbs about four amperes at 5,000 volts.

The air charged with nitrous gases which leaves the top of the tube gives up some of its heat in raising the temperature of the fresh air about to enter the tube to some 500 degrees Centigrade, and the rest is employed in steam generation. The cooled gas is then mixed with water to form nitric acid, which, after treatment with lime, results in the required manuring material. An experimental installation on these lines was opened in Christiansand (South Norway) in the spring of 1907, with a total power of 2,000 horse-power. Three ovens are at work, with a length of flame of five metres, and each absorbing 600 horse-power. Alternating current at fifty cycles is employed, and the arc burns quietly and reliably.

SUMMARY

MR. G. L. Addenbrooke, in the first of the three Cantor Lectures before the Royal Society of Arts on "The Public Supply of Electric Power in the United Kingdom," gave a comprehensive review of the present position of electric power supply in this country. A large number of statistics relating to the use of power in the various industries, and showing the extent to which electric power had been substituted for other forms, were included in the lecture. The question of the prices obtainable for power under various conditions, and the influence of diversity factor and load factor were also considered. In conclusion the lecturer dealt with the advantages of centralisation of supply, and gave some figures demonstrating the reduction in the cost per kw. of power stations with increase in capacity. (Page 56.)

MR. James Swinburne's report on the draft Home Office regulations for the use of electricity in factories has been issued. He has presented a revised code of regulations, the adoption of which he recommends to the Home Office. They are on the lines of the original draft, with certain modifications agreed upon between the objectors and the Home Office representatives, and with certain other alterations. Among the changes it will be seen that no-voltage releases on A.C. motor circuits are not insisted upon, but, on the other hand, the exposed metal parts of portable lamps other than the lamp-holders are to be earthed by a third wire in the flexible cord. Mr. Swinburne is of opinion that no man should be allowed to work alone in a dangerous place, and has amended one of the regulations so as to give the Home Office power to enforce this in any particular instance. A certain number of the regulations as to switchboards are reserved for new work, but there is no doubt that a number of switchboards and sub-stations now in use will be found to contravene the rules which are to apply to existing work. The list of exemptions does not include high pressure stations and sub-stations owned by supply authorities, and even the low-pressure side of underground sub-stations are to come under the new regulations. Service lines and apparatus and the chambers containing them on the supply side of the consumers' terminals are exempted only if no live metal is exposed "so that it may be touched." Otherwise, in general, to obtain exemption from the rules, the occupier must show that the special conditions in his premises are such as adequately to prevent danger. (Page 57.)

A PAPER was read recently before the Institution of Engineers-in-Charge on feed water and its impurities by Mr. J. B. C. Kershaw; methods of detecting and eliminating various scale-forming and corrosive impurities were described, and the subject of oil separation was dealt with. (Page 60.)

Digitized by Google

THE Board of Trade has expressed a wish that speed indicators be fitted to tramcars in certain circumstances. (Page 60.)

THE full-gauge railway from Spiez to Frutigen is to be electrically equipped on the single-phase system with a line pressure of 15,000 volts at 15 cycles. (Page 61.)

MR. Stanley Clegg (Electrical Engineer and Tramways Manager to the Corporation of Lincoln) read a Paper at last Thursday's meeting of the Institution of Electrical Engineers in which he described the "G. B." surface-contact system as in use at Lincoln, and gave particulars of the way in which various initial troubles had been overcome. It was stated that the capital cost of the system was about 10 per cent. higher than that of overhead equipment, but that the operating expenses were not higher. The causes of such live studs as had occurred were dealt with, and it was emphasised that no live stud had failed to be instantly detected by the apparatus on the cars. Several speakers in the discussion spoke highly of the system and its success under the conditions at Lincoln, but the results of the experiments with the system in London were not discussed. (Page 61.)

IN a Paper by Mr. Miles Walker on the improvement of the power factor in alternating-current systems, it is pointed out that the chief cause of low power factor is the induction motor. After explaining the method devised by Leblanc for supplying the magnetising current to the rotor by means of an auxiliary exciter, the author states that the principle could be turned to practical use, were the cost of the additional machines not excessive, and he describes a specially designed machine which could be used for this purpose. By the aid of this machine, he suggests that not only can the power factor of any induction motor be raised to unity, but a certain amount of speed variation can be obtained without serious reduction in efficiency. In the discussion it was elicited that the device in question is still in its experimental stage. The principle of charging the consumers by ampere-hour meters instead of by watt-hour meters, was also discussed. (Page 65.)

Two fire boats have recently been put into service in Chicago in which the propellers are driven by electric motors taking current from generators mounted on the same shaft as the steam turbines driving the centrifugal fire pumps. (Page 68.)

MR. L. M. Waterhouse read a Paper on conduit wiring last week before the Scottish Section of the Electrical Contractors' Association, in which he dealt with the construction of various forms of conduit material and the advisability of earthing or insulating conduit systems. (Page 69.)

A LETTER in our correspondence columns from Mr. C. E. C. Shawfield, Chief Electrical Engineer to the Corporation of Wolverhampton, continues the discussion on the article by our "Pessimistic Correspondent" on electrical power companies, and a letter from Mr. H. P. Bleckley, of the Abbey Electric Co., relates to the application of blow magnets to flame arc lamps. (Page 69.)

THERE were no specifications published by the Patent Office on Thursday last. An application by W. V. D. Kelley for the amendment of a specification describing a thermal switch for intermittently dimming lamps, has been made. Among the patents expiring during the current week is one by E. J. Preston and A. B. Gill for improvements in train-lighting systems, and another by C. A. Faure and F. King for a form of construction for storage battery plates. Short abstracts of these are given in our Patent Record. (Page 70.)

AT the Society of Road Traction Engineers on Monday, a discussion took place upon the relative advantages of petrol-electric and gear transmission for omnibuses. Mr. W. A. Stevens, of Maidstone, who opened the discussion, gave figures of running costs, &c., for the petrol-electric omnibus now being run by Messrs. Tilling in London, and compared these with the average of the remaining vehicles owned by the firm, which are all gear-driven. The total costs per mile for the petrol-electric omnibus, including depreciation on the higher capital cost during the past year, was 8·520d., whilst the cost of the gear vehicles averaged 10·106d. per mile. Mr. Stevens further stated that the petrol-electric vehicle had run 28,000 miles without any trouble whatever. Mr. A. W. Windsor spoke in favour of other forms of transmission, and doubted whether the extra capital cost of the petrol-electric was justified. Col. Crompton thought Mr. Stevens had proved his case. At the same time, if the Electrobus had not come to stay, it would be a hard fight between steam and petrol-electric. (Page 70.)

THE Devonport Corporation are considering what action to take against the Devonport and District Tramways Co. for withdrawing the cars from certain of the leased lines.—At Manchester and Liverpool the clauses in the Corporation Bills, authorising the use of the trackless trolley system, have been defeated at ratepayers' meetings.—A special committee of the Dundee Corporation is considering the installation of the trackless trolley system along the Esplanade at a cost of £5,000.—A deputation from the Bath Corporation was received privately by the Board of Trade on Thursday in regard to the proposed sale of the municipal electrical undertaking. Pending an interview with the company, no statement is to be made.—The Ilford Council is considering the question of the future management of the electricity and tramways undertakings and the engineer's salary. (Page 72.)

EXTENSIONS are contemplated at the Keighley, Nuneaton, and Watford electricity works, and electrical stores are required at Birmingham, Islington, Plymouth, and Sheffield. (Page 74.)

IT is announced that an amalgamation has been arranged between the Mexico Tramways Co. and the Mexican Light and Power Co., the previous proposals for a lease of the latter by the former having fallen through. The City and South London Railway Co.'s accounts for the half-year to December 31st, 1908, show a net profit of £48,157. A dividend of 1½ per cent. is recommended on the ordinary shares. The capital of the South Metropolitan Electric Light and Power Co. and the Victoria Falls Power Co. is to be increased. (Page 76.)

IT has been proposed to hold an engineering exhibition in Manchester in 1910. (Page 77.)

MR. Swinburne's report on the draft Home Office regulations will without doubt be acceptable to the Home Office, but it will occasion considerable annoyance to the majority of electric power suppliers and power users. Annoyance is perhaps hardly a strong enough word, for if, as is almost certain, his recommendations and draft regulations are adopted practically as they stand, the progress of electric power applications will be considerably handicapped. The long and highly-technical code of thirty-two regulations will apply equally to every "factory" under the Act, whether it be a small room with a couple of miniature motors or a large works utilising many thousand horse-power. In their eagerness for a general exemption of statutory electric power undertakings, on the one hand, or as an alternative, a general removal of the more stringent restrictions in the original Home Office draft, the objectors lost sight of the hardship inflicted upon the

Digitized by Google

smaller factories by having the same code of regulations applying to them as to the larger works. Given that the Government has set its heart upon the imposition of regulations with regard to the use of electricity in factories, a more reasonable method of applying them would have been to have one set of simple rules—practically a replica of the Board of Trade rules for 400-volt motor circuits—drafted for the small factories using medium pressure, up to a total power, say, of less than 25 h.p., and the present long and complicated code for the larger works, and those in which the supply is given at high pressure. We admit, however, that with perhaps one or two exceptions the regulations as modified by Mr. Swinburne are not harsh, and electrical engineers will do well to acquaint themselves very thoroughly with their details, so that they may reassure the nervous potential power user, and also so that they may guard themselves carefully against small technical infringements of the letter of the regulations. A further precaution will be necessary in the case of large works and of high tension installations; if the visitation of these is to be delegated to the present factory inspectors—and H.M. electrical inspector of factories, hard-working though he is, will not possibly be able to do all his own inspections—these servants of the King will have to be protected from injury during the progress of their duty. We shudder at the thought of some of these gentlemen, whose general amiability and courtesy is only equalled by their ignorance of electrical matters, being permitted free access to many of the existing generating stations and sub-stations, unless they be provided with rubber gloves, boots, and masks. Lastly, it will be noted that the question of appeal from the inspector's decision comes outside the strict scope of Mr. Swinburne's report, and we trust that the Government will give adequate facilities for this.

THE discussion at the Institution of Electrical Engineers upon Mr. Stanley Clegg's Paper on the G.B. surface-contact system, naturally lost much of its value owing to the impossibility of the Engineers of the London County Council being able to speak on their experiences, as in London the G.B. system is still, as it were, *sub judice*; nevertheless the interest taken by the London County Council authorities in Mr. Clegg's results at Lincoln, was well shown by the presence of the chairman and other members of the Highways Committee and a number of the officers and engineers of the tramway department. Mr. Clegg went thoroughly into every cause of trouble, however trivial, which had been experienced, and showed how the various causes leading to live studs were now almost eliminated, and it is important to notice that every live stud except one was detected by the apparatus on the car, and that traffic has never been interrupted from this cause. The one exception referred to was a stud on which a pony was standing when current was switched on at the commencement of working, but fortunately it was the pony and not the stud that remained alive. It came as a surprise to many to learn that the working costs at Lincoln had proved no higher than for an average overhead system, and that the initial capital cost was not more than 10 per cent. higher. Practically all the speakers in the discussion admitted that the success which has attended the use of the system at Lincoln has been largely due to its simplicity, which Mr. H. M. Sayers aptly described as the simplicity of genius. Indeed, speakers seemed to find difficulty in pointing to weaknesses, and no more serious criticism was made than to suggest that the conduit pipe would be better divided up into sections to avoid the necessity for ventilation, a modification which would do away with much of the simplicity so highly commended. The general verdict was that, at any rate for a short line with comparatively light traffic such as at Lincoln, the system was a complete success, and that, in cases where the overhead system is objected to for special reasons on a certain portion of a tramway system, the G.B. system is likely to have a considerable field of application.

ARRANGEMENTS FOR THE WEEK

FRIDAY, JANUARY 22ND.
Physical Society.
5 p.m. Meeting at Royal College of Science, Imperial Institute, South Kensington. Agenda :—(1) "The Effective Resistance and Inductance of a Concentric Main, and Methods of Computing the Ber and Bei and Allied Functions," by Dr. A. Russell; (2) "The Luminous Efficiency of a Black Body," by Dr. C. V. Drysdale; (3) "The Use of the Potentiometer on Alternate-current Circuits," by Dr. C. V. Drysdale.

MONDAY, JANUARY 25TH.
Royal Society of Arts.
8 p.m. Cantor Lecture II. :—"The Public Supply of Electric Power in the United Kingdom," by G. L. Addenbrooke.

TUESDAY, JANUARY 26TH.
Institution of Electrical Engineers: Manchester Local Section.
7.30 p.m. Meeting at the University. Paper to be read :—"Parallel Operation of Alternators," by Dr. E. Rosenberg.

WEDNESDAY, JANUARY 27*th*.
Institution of Electrical Engineers: Leeds Local Section.
7.15 p.m. Meeting at the University. Paper to be read :—"The G.B. Surface-contact System from the Tramway Manager's Point of View," by Stanley Clegg.

THURSDAY, JANUARY 28TH.
Institution of Electrical Engineers.
8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read :—"The Parallel Operation of Alternators," by Dr. E. Rosenberg.

ELECTRIC POWER SUPPLY IN THE UNITED KINGDOM

THE first of the three Cantor Lectures by Mr. G. L. Addenbrooke, on "The Public Supply of Electric Power in the United Kingdom," was delivered on Monday evening last at the Royal Society of Arts. In introducing his subject, the lecturer pointed out that there were no satisfactory statistics relating to the use of power in this country, but he mentioned the following figures from the report of the Coal Supply Commission as giving some idea of the magnitude of the problem involved. According to this report, there were used in the year 1903 about 53 million tons of coal in factories, 18 million in mines, 13 million on railways, 5 million in brick and chemical works, 28 million in iron and steel works, 15 million in gas works, and 32 million for domestic purposes. Taking these figures as a basis, and allowing for the fact that much of the above was used for heating, the lecturer estimated that the total horse-power installed in factories and mines alone was somewhat under 9 millions, including gas engines, and that there was, besides this, some 300,000 h.p. installed in lighting, power, and tramway stations. The total amount of power that would be required if all the railways in this country were driven electrically from a few large power stations, would, he thought, be well under two million horse-power. Taking the present population of the country, it could be shown that the total amount of power already installed for all purposes amounted to about ¼ h.p. per person. The United States power census of 1905 showed that the total amount of power installed there amounted to 15 million h.p., including water power, an increase of 40 per cent. over the corresponding figure for the year 1900.

Digitized by Google

Returning to the question of the power available for electrification in this country, the lecturer stated that out of the 9 million h.p. employed in the mines and factories, some 70 per cent. would be situated within the populous districts, and in the central portions of the areas of the Power Supply Companies. Allowing for the facts that some of this would be unsuitable for electric driving, and some already converted, there should be at the present moment in Great Britain over 4 million h.p. of engines installed which could be economically replaced by power supplied from the companies' stations, the remainder being in large works and collieries in the more rural districts, which could probably most advantageously produce their own electric supply. It was estimated that if electric driving were universally substituted in collieries for the plant now in use, the coal consumption, which was now more than 6 per cent. of the total coal raised, would be reduced to one-third, and even less if electric main winding were adopted. A moderate estimate of the saving of coal if electric driving were universally adopted in all industries was that the consumption would be reduced to one-half. The amount of electric power already privately installed in large mines and factories was probably of the order of one million h.p.

With regard to the difficulties due to early legislation, Mr. Addenbrooke pointed out that although holding powers over important areas, the power companies found that, as a rule, they could not supply in the most valuable portions of these areas without the consent of the local authority, and that with the exception of Newcastle and the North-East Coast generally, this had considerably retarded the progress of development. As a result, the power companies had been obliged to approach the very heavy consumers only, often at considerable distances from the centre of supply, and the local authorities had usually, on account of their limited means of distribution, approached only the smallest consumers, with the result that the supply of the small and moderately large consumers in the local authorities' areas, which was naturally the most suitable to commence with, had been neglected. Within the last two or three years, however, the local authorities had developed their power loads to a considerable degree, and in this respect it was of interest that recent evidence shows that Local Authorities in London are supplying over 26,000 h.p. of motors. The h.p. in motors connected to the Manchester Corporation mains were in excess of 25,000, while at Glasgow the total exceeded 23,000. In other towns, such as Birmingham, Sheffield, Leeds, and Bradford, the power load was also being increased. The capital invested by Local Authorities in electric supply had increased from £6,000,000 in 1899, to £42,000,000 at the present date. Of the latter sum probably £8,000,000 or £9,000,000 was for power supply apart from tramway supply. Taking the whole of the towns in the kingdom in which the electric supply was in the hands of the Local Authorities, it was probable that the total h.p. of motors connected amounted to between 250,000 and 350,000. The capital invested in Power Companies stood at present at about £7,500,000; they had some 160,000 kw. of plant installed, and over 200,000 h.p. was connected in motors. The North-East Coast Companies alone accounted for nearly half the capital, and were supplying various works to the amount of 85,000 h.p., and electrochemical works to the amount of 12,000 h.p., besides having a large lighting load. The above figures did not include the capital spent by Lighting Companies, which the lecturer estimated at £5,000,000.

Turning to the question of the price of power supplied from an outside source, the lecturer stated that for the smallest class of power users, supplied from low-pressure mains, prices of 1½d. to 1d. per unit enabled electric power to compete with the gas or oil engine, which would otherwise be installed. The price of supply to manufacturing works taking from 200 to 400 h.p. through the usual hours was from 0·85d. to 0·75d. per unit. For cotton mills where the supply was large and regular and for long hours, a price of ½d. per unit was being quoted, while for collieries the prices range between 0·7d. and 0·4d. Where the load is continuous throughout the year, as in some electrochemical works, the price quoted was even less; in one case known to the lecturer, the contract price was only 0·2d. per unit. Where coal was dear, and in towns owing to space and smoke difficulties, higher prices could be obtained. With regard to methods of charging, Mr. Addenbrooke said that although to charge with theoretic fairness, a double-sliding scale would be necessary, it was essential that the tariff should be simple to understand, and that at present there was a tendency to make contracts at fixed prices with a right of variation, if at the end of different periods the recording instruments showed that the power taken differed seriously from the contract amount, either in quantity or rate of use. Owing to the great capacity of modern machinery for taking sudden overloads, it was not so important as it used to be to consider the latter, and for this reason the ordinary integrating meters were used in conjunction with meters indicating the maximum of the average loads taken over half-hour intervals for the purpose of charging when no fixed contract was arranged.

It was interesting to consider the amount of power employed in the different industries; for example, in the light trades, this amounted to from ¼ to ½ h.p. per man employed; in engineering works from ½ to 1 h.p. per man; in mines about 1½ h.p. per man; and in the textile industries about 1 h.p. per man. As this figure was much larger in certain cases, the average might be taken as 1 h.p. per man employed. Thus, in the majority of trades, the cost of power in comparison with that of the labour employed was comparatively small; for instance, with power at 0·75d. per unit, the former amounted to ½d. per h.p.-hour, while the latter averaged at 6d. per man per hour or more; or, in other words, the wages were ten to fifteen times the cost of power. Apart from the saving in costs consequent upon the adoption of electric driving, it was to be remembered that there were the advantages of being able to obtain further power at short notice, reduced risk of breakdown, and regularity of drive. This latter, the lecturer said, was in his opinion the most important, as it led to accurate work and a larger output, especially in the textile industries and in engineering works. The lecturer concluded the above review of the present condition of electric power supply in this country with the remark that, although more had been done than most people imagined, it hardly amounted to one-fifth of what could be done in that direction.

Dealing with the advantages of power supply from central stations, the lecturer explained and considered in detail the effect of the diversity and load factors, pointing out that the diversity factor increased and the load factor decreased when a large number of consumers were supplied from a single station. In consequence the total h.p. installed in motors on the consumers' premises could be as much as 2½ to 3 times the output of the station, and that whereas the load factor was something under 25 per cent. in large manufacturing works, it was increased to about 40 or 50 per cent. by averaging up a large number of consumers. With respect to this, the lecturer emphasised the fact that it would be desirable if some agreement could be come to as to what was to be considered the maximum load on a station. For example, a suitable value would be the maximum of the averages taken over quarter-hour intervals.

The lecturer then turned to the consideration of the capital cost of large power stations, and gave the following figures as a basis for future argument, although they were not, he said, to be considered as a ready-made guide to power-station practice. Local circumstances and conditions prevented one from making generalisations of any real value.

CAPITAL COST OF ELECTRIC SUPPLY UNDERTAKINGS.

Output of station.	Cost of station.	Cost of distribution system.	Preliminary expenses, cost of finance and working capital.	Total costs.	Capital cost of undertaking.
Kw.	Per kw.	Per kw.	Per kw.	Per kw.

10,000	17	14	8	39	390,000
20,000	15	12	6	33	660,000
40,000	14	10	5	29	1,160,000

In the above table the figures in the first column, said the lecturer, represented the actual available output of the stations, so that the plant installed could be taken as one-third more than that shown for the smaller sizes to one-fourth more for the larger sizes. The chief feature of the table was the way in which it showed the reduction in cost per kw. as the size of the station increased. With regard to the figures given for distribution costs, the distribution was assumed to be up to about six miles from the station in the case of the smaller, to eight or ten miles in the case of the larger stations. These figures did not include sub-station costs for lighting supply, but did include the cost of transformers and switchgear on power consumers' premises, which amounted to from £3 to £4 per kw. The costs shown in the fourth column were unfortunately very heavy in this country, owing to the long negotiations with Local Authorities and other expenses. The lecture was concluded with a few remarks on this matter. The next lecture will be delivered on Monday, January 25th, when the working costs of power supply undertakings, and the design of the modern power station, will be dealt with.

MR. SWINBURNE'S REPORT ON THE PROPOSED HOME OFFICE REGULATIONS

THE report of Mr. James Swinburne, F.R.S., who held an inquiry in March last respecting certain objections which had been made to the draft regulations for the generation, distribution, and use of electrical energy in premises under the Factory Act which were issued by the Home Office in August, 1907, has now been published. A special report of the proceedings of the inquiry, which occupied ten days, was given in ELECTRICAL ENGINEERING, Vol. III., pages 340, 381, 449, 491, and 508, and the complete regulations, &c., in the amended form as provisionally agreed upon between the committee of objectors and the representatives of the Home Office, were given in full on page 511 (April 2nd, 1908). The following four broad considerations were discussed in addition to the consideration of the regulations in detail:—

1. Whether it was not unnecessary and inadvisable for those under the Board of Trade Regulations to be subjected to regulations imposed by another department, especially in cases in which the two sets of regulations might either overlap, or be inconsistent.
2. Whether the limits under which exemption is proposed, namely, 65 volts alternating and 130 volts direct, are not too low.
3. Whether in case of difference between a Home Office Inspector and an occupier there should be provision for resort to arbitration.
4. Whether existing plant designed and erected before the regulations were drafted should have to be altered where that would be necessary to make it comply with new regulations.

It was understood on drawing up the committee's draft regulations that these four questions were reserved, and, with reference to the draft itself, Mr. Swinburne remarks that as all the objectors were not represented on the committee, the draft could not be taken as binding on either the objectors or the Home Office. In his report, therefore, he considers it his duty to recommend any alterations which he believes to be advisable either in the direction of greater or less strictness.

With regard to the question of the overlapping of the Board of Trade Regulations intended solely to secure the safety of the public, with the proposed regulations which are directed towards the safety of workmen, it is stated that, after the evidence of the electrical adviser to the Board of Trade, the contention that the Home Office rules should not apply to all factories was dropped, on the understanding that the Board of Trade intend to alter their regulations to avoid overlapping. The exact points of overlapping are discussed in some detail, and finally Mr. Swinburne recommends that the Board of Trade be asked to alter Regulation A 1, so that factories, workshops, and mines can be supplied at pressures exceeding the limit of low pressure without complying with the conditions (*a*) and (*b*) following that regulation. That they be asked to alter A 2, so that factories, workshops, and mines, and docks and warehouses, as far as they are under the Home Office, shall be exempted; and that workshops, as well as factories and mines, should be allowed to receive extra high pressure supply according to the conditions of Regulation A 3; and that the necessary alterations be made in cases where the regulations are incorporated in Acts of Parliament or Provisional Orders.

He also recommends that no alterations of, or exemptions from, the regulations as to extra high pressure be asked for, though this leaves some overlapping in fact.

The question of arbitration, appeal, or other protection is discussed at considerable length, but no formal recommendation is made. Certain hardships which might arise are recognised, however, and after recapitulation of some of the arguments brought forward at the inquiry, he informally recommended that before prosecuting or instituting proceedings on the ground that the regulations are not complied with, the Home Office should serve notice on the occupier that he is not complying with the regulations, and should not, except in special cases, proceed until at least thirty days after serving notice, during which time any representations or statements on the part of the occupier should be considered by the Home Office.

It is also recommended that an exemption be added to the effect that the Secretary of State may direct that any particular regulation or regulations which he specifies shall not apply in any case or set of cases in which he gives exemption, on the ground that, in his opinion, safety is otherwise practically secured, or of emergency or special circumstances, on such conditions as the Secretary of State may prescribe.

The definitions, exemptions, and regulations, as modified by Mr. Swinburne, are, for the sake of easy reference, given in full below. A comparison with the committee's draft, published in April, will show that there are considerable alterations. Many of these are matters of wording, but some important alterations have been made in respect of matters which were discussed at considerable length at the inquiry. Attention is drawn to some of these in the latter part of this article.

DEFINITIONS.

"*Pressure*" means the difference of electrical potential between any two conductors, or between a conductor and earth as read by a hot wire or electrostatic voltmeter.

"*Low Pressure*" means a pressure in a system normally not exceeding 250 volts where the electrical energy is used.

"*Medium Pressure*" means a pressure in a system normally above 250 volts, but not exceeding 650 volts, where the electrical energy is used.

"*High Pressure*" means a pressure in a system normally above 650 volts, but not exceeding 3,000 volts, where the electrical energy is used or supplied.

"*Extra-high Pressure*" means a pressure in a system normally exceeding 3,000 volts, where the electrical energy is used or supplied.

"*System*" means an electrical system in which all the conductors and apparatus are electrically connected to a common source of electromotive force.

"*Conductor* means an electrical conductor arranged to be electrically connected to a system.

"*Apparatus*" means electrical apparatus, and includes all apparatus, machines, and fittings in which conductors are used, or of which they form a part.

(The definition of "Cable" has been deleted.)

"*Circuit*" means an electrical circuit forming a system or branch of a system.

"*Insulating stand*" means a floor, platform, stand, or mat
"*Insulating screen*" means a screen
"*Insulating boots*" means boots
"*Insulating gloves*" means gloves
} of such size, quality, and construction according to the circumstances of the use thereof, that a person is thereby adequately protected from danger.

"*Covered with insulating material*" means adequately covered with insulating material of such quality and thickness that there is no danger.

"*Bare*" means not covered with insulating material.

"*Live*" means electrically charged.

"*Dead*" means at, or about, zero potential, and disconnected from any live system.

"*Earthed*" means connected to the general mass of earth in such manner as will ensure at all times an immediate discharge of electrical energy without danger.

"*Substation*" means any premises, or that part of any premises, in which electrical energy is transformed or converted to or from pressure above medium pressure, except for the purpose of working instruments, relays, or similar auxiliary apparatus; which are also large enough for a person to enter after the apparatus is in position.

"*Switchboard*" means the collection of switches, or fuses, conductors and other apparatus in connection therewith, used for the purpose of controlling the current or pressure in any system or part of a system.

"*Switchboard passage-way*" means any passage-way or compartment large enough for a person to enter, and used in connection with a switchboard when live.

"*Authorised person*" means the occupier or a contractor for the time being under contract with the occupier or a person employed, appointed, or selected by the occupier, or by a contractor as aforesaid, to carry out certain duties incidental to the generation, transformation, distribution, or use of electrical energy, such occupier, contractor, or person being competent to carry out those duties.

D

Digitized by Google

"*Danger*" means danger to health or danger to life or limb from shock, burn, or other injury to persons employed, or from fire attendant upon the generation, transformation, distribution, or use of electrical energy.

"*Public supply*" means the supply of electrical energy (*a*) by any local authority, company, or person authorised by Act of Parliament or Provisional Order confirmed by Parliament, or by licence or Order of the Board of Trade to give a supply of Electrical Energy; or (*b*) otherwise under Board of Trade Regulations.

EXEMPTIONS.

1. Nothing in Regulations 2, 3, 4, 7, 9, 10, 11, 15, 16, 17, 21, 22, 23, 24, 25, 26, 29, 30, 31, and 32 shall apply; unless on account of special circumstances the Secretary of State shall give notice to the occupier that this exemption does not apply :—

(*a*) To any system in which the pressure does not exceed low pressure direct or 125 volts alternating.

(*b*) In any public supply generating stations, to any system in which the pressure between it and earth does not exceed low pressure.

(*c*) In any above-ground substations for public supply, to any system not exceeding low pressure.

4. Nothing in these Regulations shall apply to any service lines or apparatus on the supply side of the consumers' terminals or to any chamber containing such service lines or apparatus where the supply is given from outside under Board of Trade Regulations; provided always that no live metal is exposed so that it may be touched.

5. If the occupier can show with regard to any requirement of these Regulations, that the special conditions in his premises are such as adequately to prevent danger, that requirement shall be deemed to be satisfied; and the Secretary of State may by Order direct that any class of special conditions defined in the Order shall be deemed for the purposes of all or any of the requirements of these Regulations adequately to prevent danger, and may revoke such Order.

6. Nothing in these Regulations shall apply to any process or apparatus used exclusively for electro-chemical or electro-thermal or testing or research purposes; provided such process be so worked and such apparatus so constructed and protected and such special precautions taken as may be necessary to prevent danger.

7. The Secretary of State may, by Order, exempt from the operation of all or any of these Regulations any premises to which any special rules or regulations under any other Act as to the Generation, Transformation, Distribution or Use of Electrical Energy apply; and may revoke such Order.

8. Nothing in these Regulations shall apply to domestic factories or domestic worshops.

9. The Secretary of State may, if satisfied that safety is otherwise practically secured, or that exemption is necessary on the ground of emergency or special circumstances, grant such exemption by order, subject to any conditions that may be prescribed therein; and may revoke such order.

REGULATIONS.

1. All apparatus and conductors shall be sufficient in size and power for the work they are called upon to do, and so constructed, installed, protected, worked, and maintained as to prevent danger so far as is reasonably practicable.

2. All conductors shall either be covered with insulating material, and further efficiently protected where necessary to prevent danger, or they shall be so placed and safeguarded as to prevent danger so far as is reasonably practicable.

3. Every switch, switch-fuse, circuit-breaker, and isolating link shall be :—(*a*) So constructed, placed, or protected as to prevent danger; (*b*) so constructed and adjusted as accurately to make and to maintain good contact; (*c*) provided with an efficient handle or other means of working, insulated from the system, and so arranged that the hand cannot inadvertently touch live metal; (*d*) so constructed or arranged that it cannot accidentally fall or move into contact when left out of contact.

4. Every switch intended to be used for breaking a circuit and every circuit-breaker shall be so constructed that it cannot with proper care be left in partial contact. This applies to each pole of double-pole or multi-pole switches or circuit-breakers.

Every switch intended to be used for breaking a circuit and every circuit-breaker shall be so constructed that an arc cannot accidentally be maintained.

5. Every fuse and automatic circuit-breaker used instead thereof shall be so constructed and arranged as effectively to interrupt the current before it so exceeds the working rate as to involve danger. It shall be of such construction or be so guarded or placed as to prevent danger from over-heating, or from arcing or the scattering of hot metal or other substance when it comes into operation. Every fuse shall be either of such construction or so protected by a switch that the fusible metal may be readily renewed without danger.

6. Every electrical joint and connection shall be of proper construction as regards conductivity, insulation, mechanical strength and protection.

7. Efficient means, suitably located, shall be provided for cutting off all pressure from every part of a system, as may be necessary to prevent danger.

8. Efficient means suitably located shall be provided for protecting from excess of current every part of a system, as may be necessary to prevent danger.

9. Where one of the conductors of a system is connected to earth, no single-pole switch other than a link for testing purposes or a switch for use in controlling a generator shall be placed in such conductor or any branch thereof.

A switch, or automatic or other cut-out may, however, be placed in the connection between the conductor and earth at the generating station for use in testing and emergencies only.

10. Where one of the main conductors of a system is bare and uninsulated, such as a bare return of a concentric system, no switch, fuse, or circuit-breaker shall be placed in that conductor, or in any conductor connected thereto, and the said conductor shall be earthed.

Nevertheless, switches, fuses, or circuit-breakers may be used to break the connection with the generators or transformers supplying the power, provided that in no case of bare conductor the connection of the conductor with earth is thereby broken.

11. Every motor, converter and transformer shall be protected by efficient means suitably placed, and so connected that all pressure may thereby be cut off therefrom and from all apparatus in connection therewith, provided, however, that where one point of the system is connected to earth, there shall be no obligation to disconnect on that side of the system which is connected to earth.

12. Every electrical motor shall be controlled by an efficient switch or switches for starting and stopping, so placed as to be easily worked by the person in charge of the motor.

In every place in which machines are being driven by any electric motor, there shall be means at hand for either switching off the motor or stopping the machines if necessary to prevent danger.

13. Every flexible wire for portable apparatus for alternating currents or for pressures about 150 volts direct current shall be connected to the system either by efficient permanent joints or connections, or by a properly constructed connector.

In all cases where the person handling portable apparatus or pendant lamps with switches, for alternating current or pressures above 150 volts direct current, would be liable to get a shock through a conducting floor or conducting work or otherwise if the metal work of the portable apparatus became charged the metal work must be sufficiently earthed; and any flexible metallic covering of the conductors shall be itself efficiently earthed and shall not itself be the only earth connection for the metal of the apparatus. And a lampholder shall not be in metallic connection with the guard or other metal work of a portable lamp.

In such places and in any place where the pressure exceeds low pressure, the portable apparatus and its flexible wire shall be controlled by efficient means suitably located, and capable of cutting off the pressure, and the metal work shall be efficiently earthed independently of any flexible metallic cover of the conductors, and any such flexible covering shall itself be independently earthed.

14. The general arrangement of switchboards shall, so far as reasonably practicable, be such that :—

(*a*) All parts which may have to be adjusted or handled are readily accessible.

(*b*) The course of every conductor may where necessary be readily traced.

(*c*) Conductors not arranged for connection to the same system are kept well apart and can where necessary be readily distinguished.

(*d*) All bare conductors are so placed or protected as to prevent danger from accidental short circuit.

15. Every switchboard having bare conductors normally so exposed that they may be touched, shall if not located in an area or areas set apart for the purposes thereof where necessary be suitably fenced or enclosed.

No person except an authorised person, or a person acting under his immediate supervision, shall for the purpose of carrying out his duties have access to any part of such area.

16. All apparatus appertaining to a switchboard and requiring handling, shall so far as practicable be so placed or arranged as to be operated from the working platform of the switchboard, and all measuring instruments and indicators connected therewith shall, so far as practicable, be so placed as to be observed from the working platform. If such apparatus be worked or observed from any other place, adequate precautions shall be taken to prevent danger.

17. At the working platform of every switchboard and in every switchboard passage-way, if there be bare conductors exposed or arranged to be exposed when live so that they may be touched, there shall be a clear and unobstructed passage of ample width and height with a firm and even floor. Adequate means of access, free from danger, shall be provided for every switchboard passage-way.

The following provisions shall apply to all such switchboard working platforms and passage-ways constructed after January 1st, 1909, unless the bare conductors, whether overhead or at the sides of the passage-ways, are otherwise adequately pro-

Digitized by Google

tected against danger by divisions or screens or other suitable means :—

(*a*) Those constructed for low-pressure and medium-pressure switchboards shall have a clear height of not less than 7ft., and a clear width measured from bare conductor of not less than 3 ft.

(*b*) Those constructed for high-pressure and extra high-pressure switchboards other than operating desks or panels working solely at low-pressure shall have a clear height of not less than 8ft. and a clear width measured from bare conductor of not less than 3 ft. 6 in.

(*c*) Bare conductors shall not be exposed on both sides of the switchboard passage-way unless either the clear width of the passage is in the case of low-pressure and medium-pressure not less than 4 ft. 6 in., and in the case of high-pressure and extra high-pressure not less than 8ft., in each case measured between bare conductors, or the conductors on one side are so guarded that they cannot be accidentally touched.

18. In every switchboard for high-pressure or extra high-pressure :—

(*a*) Every high-pressure and extra high-pressure conductor within reach from the working platform or in any switchboard passage-way shall be so placed or protected as adequately to prevent danger.

(*b*) The metal cases of all instruments working at high-pressure or extra high-pressure shall be either earthed or completely enclosed with insulating covers.

(*c*) All metal handles of high-pressure and extra high-pressure switches, and, where necessary to prevent danger, all metal gear for working the switches shall be earthed.

(*d*) When work has to be done on any switchboard, then, unless the switchboard be otherwise so arranged as to secure that the work may be carried out without danger; either (i) the switchboard shall be made dead, or (ii) if the said switchboard be so arranged that the conductors thereof can be made dead in sections, and so separated by permanent or removable divisions or screens from all adjoining sections of which the conductors are alive, that work on any section may be carried out without danger that section on which work has to be done shall be made dead.

19. All parts of generators, motors, transformers, or other similar apparatus, at high-pressure or extra high-pressure, and within reach from any position in which any person employed may require to be, shall be, so far as reasonably practicable, so protected as to prevent danger.

20. Where a high-pressure or extra high-pressure supply is transformed for use at a lower pressure, or energy is transformed up to above low pressure suitable provision shall be made to guard against danger by reason of the lower-pressure system becoming accidentally charged above its normal pressure by leakage or contact from the higher-pressure system.

21. Where necessary to prevent danger, adequate precautions shall be taken either by earthing or by other suitable means to prevent any metal other than the conductor from becoming electrically charged.

22. Adequate precautions shall be taken to prevent any conductor or apparatus from being accidentally or inadvertently electrically charged when persons are working thereon.

23. Where necessary adequately to prevent danger, insulating stands or screens shall be provided and kept permanently in position, and shall be maintained in sound condition.

24. Portable insulating stands, screens, boots, gloves, or other suitable means shall be provided and used when necessary adequately to prevent danger, and shall be periodically examined by an authorised person.

25. Adequate working space and means of access, free from danger, shall be provided for all apparatus that has to be worked or attended to by any person.

26. All those parts of premises in which apparatus is placed shall be adequately lighted to prevent danger.

27. All conductors and apparatus exposed to the weather, wet, corrosion, inflammable surroundings or explosive atmosphere, or used in any process or for any special purpose other than for lighting or power, shall be so constructed or protected, and such special precautions shall be taken as may be necessary adequately to prevent danger in view of such exposure or use.

[Regulation 28 has been deleted.]

29. No person except an authorised person or a competent person acting under his immediate supervision shall undertake any work where technical knowledge or experience is required in order adequately to avoid danger; and no such person shall work alone in any case in which the Home Office directs that he shall not. No person except an authorised person, or a competent person over 21 years of age acting under his immediate supervision, shall undertake any repair, alteration, extension, cleaning, or such work where technical knowledge or experience is required in order to avoid danger, and no one shall do such work unaccompanied.

Where a contractor is employed, and the danger to be avoided is under his control, the contractor shall appoint the authorised person, but if the danger to be avoided is under the control of the occupier, the occupier shall appoint the authorised person.

30. Instructions as to the treatment of persons suffering from electric shock shall be affixed in all premises where electrical energy is used other than at low pressure, generated or transformed above low pressure, and in any premises at low pressure in which the Home Office directs that they shall be affixed.

31. Every sub-station shall be substantially constructed, and shall be so arranged that no person other than an authorised person can obtain access thereto otherwise than by the proper entrance, or can interfere with the apparatus or conductors therein from outside, and shall be provided with efficient means of ventilation and be kept dry.

32. Every sub-station shall be under the control of an authorised person, and none but an authorised person or a person acting under his immediate supervision shall enter any part thereof where there may be danger.

33. Every underground sub-station not otherwise easily and safely accessible shall be provided with adequate means of access by a door or trap-door, with a staircase or ladder securely fixed and so placed that no live part of any switchboard or any bare conductor shall be within reach of a person thereon : Provided, however, that the means of access to such sub-station shall be by a doorway and staircase; (*a*) if any person is regularly employed therein, other than for inspection and cleaning; or (*b*) in any such sub-station not of ample dimensions, either if there is moving machinery therein, other than ventilating fans, or if there is extra high-pressure therein.

It will be noticed that the definition of low pressure has been altered, in accordance with the Departmental Rules under the Coal Mines Regulation Act, so as to avoid the generating end of a 250-volt line giving a supply to lamps at 240 volts being classed as medium pressure, while the other parts of the circuit are low pressure, and, similarly, the limits of high and extra-high pressures relate to parts where the energy is used. The definition of a substation has also been slightly changed, and that of public supply is re-worded.

One of the most important changes is the exemption in the raising of the limits below which the principal clauses of the regulations do not apply from 130 volts continuous and 65 volts alternating to "low pressure" direct (*i.e.*, up to 250 volts) and 125 volts alternating. In Mr. Swinburne's opinion the exemption should be fixed at low pressure for direct current, that is to say, not exceeding 250 by more than a few volts, and 125 for alternating current. This will tend to obviate accidents likely to occur on 200 to 250 volts alternating, this pressure being very common on lighting and power circuits; but it will not hamper the use of 100 volts alternating, which is used almost exclusively for lighting.

It would be well, he continues, if all conductors not earthed, that may be alive, were painted some bright colours such as red and blue, or aluminium white. He cannot, he says, recommend the insertion of such a regulation, however, as, though painting was mentioned, it was not discussed. It is open, however, to the department to recommend this practice.

The second exemption in the committee's draft, which provided for the exemption of such undertakings as supply stations, docks, railways, and from the obligation of earthing uninsulated returns and other requirements contained in Regulations 7, 8, 9, and 10, as they stood, has been deleted, and Regulations 9 and 10 amended.

Mr. Swinburne points out that in the case of three-wire distribution it is advisable to earth the middle wire at the generating station. It is also usual to earth the neutral point of a polyphase system. The earth connection is made through a resistance, and a switch and sometimes automatic gear are also provided. If a factory takes, say, 250 volts alternating on one side of a three-wire supply, one terminal will be at 250 volts, the other at zero. It is advisable to make sure that no switch is put into the earthed circuit, otherwise the safety due to the earthing at the generating station is abolished. This is also especially important when the conductors, normally earthed, are bare. To meet this, as most factories take electric supply from outside, the simplest way was to frame such regulations as 9 and 10 dealing with the consumers' circuits, and to enable the generating stations to carry out their part of the arrangement by exempting them. As outside stations are practically always under statutory powers, the exemption evidently was drawn up specifying them as a matter of simplicity.

Exemption 3, which exempted motor-generators from Regulation 12, has also been deleted in view of the proposed alterations to the latter.

The exemptions numbered 7, 8, and 9 are additional ones, which have now been inserted.

The word "switch-fuse" has been inserted into Regulation 3, and an addition has been made to Regulation 4 in order to include double-pole switches. The alterations to Reguations 9 and 10 are in connection with the exemptions already mentioned. Mr. Swinburne points out that in a factory which runs on a three-wire direct or a three-phase system, it may be advisable to run generally with the neutral earthed, but in

Digitized by Google

case of a serious earth on one of the other mains, it may be advisable to run with the neutral earth disconnected, rather than put out the lights suddenly or shut down.

The exemption of "domestic factories" from the regulations will apparently only apply to those cases in which electricity is used for lighting only; if a single motor is used on the premises, they are, it appears, no longer a "domestic factory."

Regulation 12 gave rise to much discussion; in the form approved by the committee, the second paragraph read as follows:—"Where necessary, to prevent danger through the automatic re-starting of a motor, every electrical motor or group of electrical motors shall be protected by a release which will automatically break the circuit if the current is interrupted, such release being suitably placed with regard to the danger to be prevented. Provided that no release shall be required for any motor which has an attendant constantly at the controller of such motor while at work." Mr. Swinburne considers it unnecessary to require no-voltage releases to be placed on every starter, and points out that if an occupier refuses to put a no-power release on a motor driving such a machine as a newspaper press, the inspector can insist on its being fenced so that the workman cannot get in when the machine is liable to start automatically.

The strictness of the last paragraph of Regulation 12 has been modified by the addition of the words, "if necessary to prevent danger." Regulation 13 has been considerably altered and made much more definite, particularly in regard to hand lamps. Mr. Swinburne considers that the second paragraph as it stood was rather general, and continues in the report:—"It seems better to say definitely, that in all cases where the person handling portable apparatus would be liable to get a shock through damp floor or otherwise if the metal work became charged, the metal work must be efficiently earthed if the pressure is alternating, or above 150 volts direct current. If the pressure is above low pressure, the metal work must be efficiently earthed in all cases. This would mean efficiently earthing by a third wire in the flexible. Sometimes the flexibles are protected by metallic flexible tubing, and this is earthed. It should be earthed on its own account, but should not be used as the sole means of earthing the metal work of a tool or lamp, as it is very apt to get disconnected at the ends. There should, therefore, be a third earth wire, and the flexible covering should be earthed at the socket end, and connected to the metal of the apparatus too." It is pointed out that most of the objections to Regulation 14 solve themselves if the pressure exemption goes up to 125 volts. Regulation 18 has been re-worded so as to make clear the obligation to render a switchboard dead before working on it.

Important additions are made to Regulation 29, providing that no man shall work unaccompanied in a dangerous place in which the Home Office directs that he shall not. Mr. Swinburne points out that a man working at repairs in, say, an underground sub-station, may get a shock and be killed, whereas if another man were with him he might be released, or help might be obtained by telephone or by shouts, and the man might be treated properly. It seems advisable, he adds, that the authorised person, who is presumably a journeyman, should not employ an apprentice or an untrained labourer as an assistant in dangerous work.

Regulation 30 was left to be dealt with by the Commissioner, who considers that it should only apply in the case of low pressure unless the Home Office considers it should apply in any particular or class of case, and gives notice to that effect. Regulation 34 of the committee's draft, requiring periodical inspections by an authorised person, has been deleted.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—*Member:* F. Bourne. *Associate Members:* F. C. Anderson, H. K. Benson, A. Bott, A. G. Collis, Capt. S. H. Cowan, R.E., E. E. Dalglish, Lieut. A. E. Davidson, R.E., W. A. Gilbert, C. L. Glen-Bott, N. Harrison, A. H. Horsfield, A. H. Nicholson, S. L. R. Price, W. H. Shaw, E. A. Shrimpton, C. H. Smith, S. W. Spendlove, J. W. Sutton. *As Associates:* M. M. Bear, Comm. J. O. Hatcher, R.N., Capt. J. Hunter, R.E.

The Pollak-Virag Telegraph System.—Some years ago some experiments were carried out by the postal authorities to determine the commercial practicability of the Pollak-Virag system of high-speed telegraphy, but the results were not very satisfactory. According to the *Standard*, some further experiments are to be conducted shortly by the French and British Governments, the inventors having claimed that improvements made in the system since the previous experiments have overcome all the difficulties experienced. It is stated that a speed of 40,000 words per hour can be attained by the apparatus in its present form. The principle of operation was described in ELECTRICAL ENGINEERING, Vol. IV., page 146.

FEED WATER AND ITS IMPURITIES

A PAPER was read by Mr. John B. C. Kershaw last Wednesday, before the Institution of Engineers-in-Charge, on "Feed Water and its Impurities." The impurities found in natural water are determined largely by its source, and may be scale-forming or non-scale-forming, corrosive or non-corrosive. The scale-forming salts are calcium and magnesium carbonates and sulphates; silica is also found as an ingredient of many very hard scales. The general corrosive impurities are carbonic acid, oxygen, and chlorine, these gases being liberated in a nascent or ionised condition when the water containing them in either the free or the combined state is heated above its boiling point under certain conditions. Another class of corrosive impurity sometimes met with arises from the use in excess of certain water-softening chemicals, and finally the most dangerous impurity is oil. Some methods of testing for impurities were mentioned in the Paper, and daily tests with litmus for alkalinity, and with petrol-ether for oil, were recommended. This latter test is made as follows:—A sample of water (at least one pint) is placed in a separating funnel provided with a glass stopcock and stopper, and is shaken up vigorously with 20 c.c. of petrol-ether. The oil, if any be present, is dissolved by the latter, and on standing, the petrol-ether solution of the oil will separate itself from the heavier water, and will float upon its surface. The water is then run off by the stopcock; the ether solution is emptied into a porcelain basin or saucer, and is placed in a warm place free from dust, for the ether to evaporate. The residue will be the oil contained in the pint of water, and this test therefore provides a useful check upon the efficient working of the oil separator.

Oil may be removed in several ways, of which filtration is the simplest, but in some cases the oil is so finely divided and emulsified that it must be submitted to any process of coagulation or electrical treatment, by which a flocculent precipitate is formed which carries down the particles of oil. When the boilers are scaled also the scale can be tested by heating a small portion in a flame; if it chars or gives off a smell of burnt organic matter, then oily matter has been present. Free mineral acids should be neutralised by carbonate of soda. Impurities which produce scale may be partly removed by pre-heating, but the addition of chemicals is required to effect the removal of more troublesome calcium and magnesium salts. These salts may be removed by treating with sodium carbonate; barium hydrate has also been recommended.

The latter part of the Paper was devoted to practical examples showing the effect of various impurities in practice, including serious cases of pitting and scaling. The electrolytic method of preventing corrosion of condenser tubes employed at the Long Island City Power House was also mentioned. Here a small motor-generator provides a counter E.M.F. of about 0·6 volts to neutralise the E.M.F. set up by the metals of the condenser body and tubes. In conclusion, some experiments with a model boiler regarding the prevention of priming were described.

Electrical Standardising, Testing, and Training Institution.—A special series of lectures upon "Electric Motors for Alternating Circuits" is to be delivered to the third-year students during the ensuing term by Mr. H. M. Hobart.

Speed Indicators on Tramcars.—The following letter, signed by G. R. Askwith, has been sent by the Board of Trade to all the tramway and light railway authorities in the United Kingdom:—"I am directed by the Board of Trade to state that representations have been made to them from time to time in favour of requiring all cars on tramways and light railways on public roads to be fitted with an apparatus for indicating the speed at which they are travelling. It would appear from the circumstances of certain accidents occurring on tramways, and from other evidence, that the maximum speeds fixed by the Board's regulations are frequently exceeded in practice, and one of the arguments urged in favour of the adoption of speed indicators is the difficulty of estimating speed without their aid. There are, however, certain difficulties connected with the introduction of speed indicators, and the Board do not at present consider it advisable to require them to be fitted to all cars. As it would seem to be the fact that motormen are frequently unable to judge with accuracy the speed at which they are driving, and that excessive speeds are attributable to this cause, the Board are advised that it is desirable that a certain proportion of the cars on all systems shall be fitted with speed indicators, to enable motormen to be trained in judging speeds. The Board would be glad to learn at an early date that this recommendation will be adopted on your lines, and in due course the precise steps that have been taken and the particular form of indicator selected."

ELECTRIFICATION OF THE SPIEZ-FRUTIGEN RAILWAY

THE Berner Alpenbahn-Gesellschaft has decided on the electrification of their full gauge line from Spiez to Frutigen, and has placed a contract for three motor-cars, one locomotive, and the overhead equipment with "Elektrische Bahnen, Zurich," which is the Swiss agency for the Machinenfabrik Oerliken and Siemens-Schuckertwerke for full-gauge electric railways in Switzerland. The system will be the same as adopted by the Oerliken Company for the Seebach-Wettingen line, and is also similar to that to be used for the Wiesental railway, an order for the electrical equipment of which has recently been placed by the State railways of Baden.

The Spiez-Frutigen line will be worked by single-phase current with a frequency of 15 cycles per second, and a line voltage of 15,000 volts. Current will be supplied by the Vereinigten Kander and Hagneckwerke A.G., and for this purpose two additional generating sets of 3,200 h.p. each will be installed in the power station at Spiez. Each set will consist of a turbine direct coupled to a single-phase generator for a pressure of 16,000 volts. The contact wire will be supported by a catenary suspension in the centre of the track at a height of approximately 21 ft. above the rails, and the current will be conveyed to the motor-cars and locomotives by means of bow collectors.

The motor-cars will be provided with two bogies. They will be about 65 ft. long and provide seating capacity for 64 passengers.

The maximum gradient on the Spiez-Frutigen line is 1·55 per cent., but the maximum gradient on the Loetschberg Railway, which forms the continuation of the former line, ranges up to 2·7 per cent. The motor-cars will, therefore, be so designed that they can accommodate four single-phase motors of an aggregate output of 880 h.p. As long, however, as electric operation is confined to the Spiez-Frutigen section, only two motors will be provided. The weight of the fully equipped motor-car will be 55 tons, and the capacity of the motors is sufficient to haul a train of a total weight of 160 tons up a gradient of 2·7 per cent. at a speed of 28 miles per hour, or a train weighing 240 tons up a gradient of 1·5 per cent. at the same speed.

The locomotive will have a total motor capacity of 2,000 h.p., and will be capable of hauling trains of 310 and 500 tons up the gradients of 2·7 and 1·55 per cent. respectively at a speed of 25 miles per hour. Each of the two bogies is provided with a 1,000 h.p. single-phase motor, which drives the three axles by means of gearing and coupling rods. These motors will be the largest single-phase commutator motors yet built. The whole weight of the locomotive (approximately 86 tons) will be utilised for adhesion. The motor-cars and locomotive will be equipped with transformers for reducing the line voltage of 15,000 volts to the variable voltage required for the motors when running at different speeds. The maximum speed for the motor-cars and the locomotive has been fixed at 43½ miles per hour. The motor-cars are intended for regular service on the Spiez-Frutigen section, while the locomotives are primarily intended for experimental purposes in view of the adaptation of electric traction on the main line later on. The work in connection with the electrification is being directed by Herr Thomann, of Berne, the Consulting Engineer.

THE G.B. SURFACE-CONTACT SYSTEM AT LINCOLN

MR. STANLEY CLEGG (Electrical Engineer and Tramways Manager to the Corporation of Lincoln), read a Paper, entitled "The 'G.B.' System from a Tramway Manager's Point of View," at last Thursday's meeting of the Institution of Electrical Engineers, in which he gave his experiences with the system as installed on the Lincoln Tramways.

The author recapitulated the considerations which had led to the choice of the system, and mentioned that the agreement with the "G.B." Company contained, among other things, the following conditions :—That the collectors on the cars should be of such type as to allow the cars to be run up to a rate of 16 miles an hour without undue sparking, the steadiness of the car lighting to be the criterion. That the electrical energy necessary for exciting the magnets of the collecting apparatus should not exceed 480 watt-hours per hour per car, and that the total consumption per car-mile should not exceed 1·3375 units. That not more than 18 studs in any year, for a period of ten years, should become charged with electricity at such time as when not in use for supplying energy to a passing car, and should remain undetected by the car that has caused them to become so charged. That the cost of maintenance of the special apparatus peculiar to the "G.B." system in efficient working order and repair should not exceed an average of £30 per mile of track per annum during a period of ten years. In the event of the system failing to satisfy the Corporation on the above points, or proving unsatisfactory for any other reason, the Corporation to have the right to retain the amount in the tender representing the cost of the "G.B." equipment, which moneys might be used for installing such other system as might seem to be desirable.

The system was installed, and the whole of the work completed ready for running, between July 1st and the middle of November, 1905, and after inspection by the Board of Trade was opened for service on November 23rd. The "G.B." surface-contact system was described in some detail in ELECTRICAL ENGINEERING (Vol. IV., page 11), but the following notes condensed from Mr. Clegg's Paper will be of interest.

The supply cable *A* (on Figs. 1 and 2) consists of galvanised iron wires stranded together on a jute core, over which are threaded galvanised steel sleeves A_1, which make a smooth face for the carbon contacts to bed on. Access boxes are placed at intervals.

The conduit *C*, in which the cable is carried, consists of sections of ordinary glazed vitrified 5-in. stoneware pipe. A special bituminous joint is used to connect the separate sections, and a tee-piece *B*, is cemented on to a special section where a stud is required. The conduit is completely embedded in concrete. The total depth of excavation necessary does not exceed 18 in. The insulators, *D*, which carry the cable, are of the roller pattern, with long creeping surface and constricted cross-section. The ends of the galvanised steel pins, *E*, project through the conduit, and are connected together by means of an earthed iron strip, *F*, which is connected at intervals to the rails. Thus any current leaking from the source of supply is bound to pass into the pin, and thence through the connection to the rails, thus completely shielding the stud from leakage currents.

The studs have cast-iron heads, *G*, the top surfaces of which are level with the rest of the paving. The joint between the vertical portion of the stud *H* and the upright stoneware *B*, into which it passes, is made by filling in the interspace between them with bitumen supported on a packing of jute yarn, C_1. Bitumen is also run in round the stud heads, filling any spaces between the granite blocks and the studs. The vertical part of the stud *H*, which projects downwards into the upright piece of pipe, is forked at the lower end and lined with brass *I*. Within the fork is mounted a moving part; this consists of a piece of enamelled iron *J* suspended freely by means of an insulated copperd steel spring *K* from the top of the fork. Its movement is limited by a brass pin *L*, which passes through a slot and is riveted into the jaws of the fork. From the lower end of the moving-piece two horns *M* project outwards, supporting a copper clip M_1 to hold a carbon-contact block. Flexible copper leads *O* connect the moving part with the main portion of the stud. When the magnet carried by a car passes over the stud, the moving-piece *J* is magnetically attracted towards the cable against the pull of the spring *K*, so that the carbon block *N* is in contact with the cable *A*, and current passes from the cable through the carbon *N* and flexible copper connections *O* to the

Digitized by Google

stud head G, where it is collected by the car. The horns M on the moving-piece J, which rises rapidly after the influence of the magnet is withdrawn, strike the copper clip M a smart blow in any case where a slight adhesion has taken place between the carbon contact and the cable, due to the passage of current. This blow is found to break down the adhesions that occur in practice.

The magnet P is suspended rigidly from the car. The coils (*see* Fig. 3) and the battery are connected so that when the motors are taking current, their current, when small, assists the battery in exciting the magnet, and when large also re-charges the battery, as can be gathered from the diagram of connections. The collector consists of a chain of iron links Q pinched on a wire rope R, fixed at each end and spring suspended within one

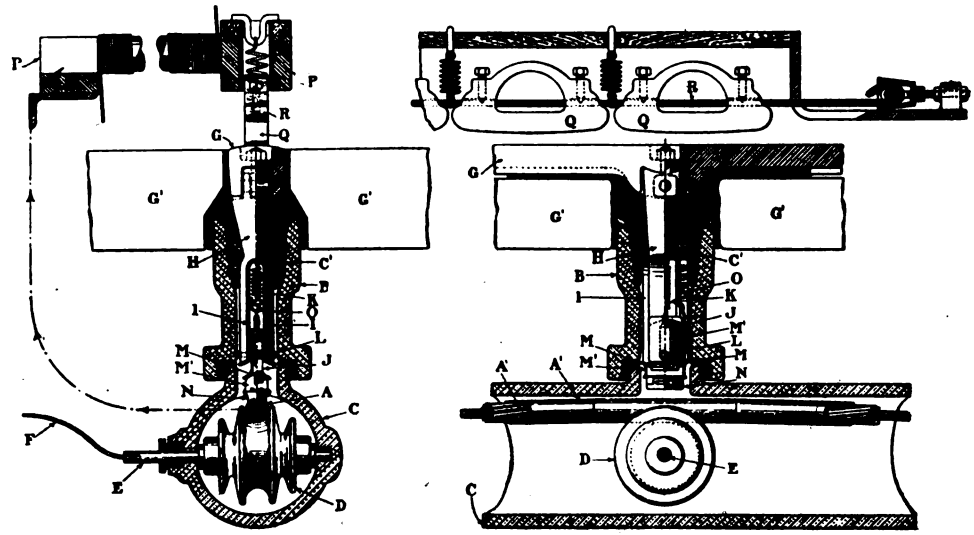

FIG. 1.—SECTIONS OF CONDUIT PIPE, STUD, AND COLLECTING CHAIN.

pole of the magnet, the bottom face of which moves over the stud head. When the pole of the magnet P passes over a stud head, the attraction causes the links Q to move down and make contact with it; as each link reaches the end of a stud, it is drawn up out of contact with the road by the spring. If a stud be left "live" due to any fault of the switching mechanism, a safety brush S, carried by the car, will cause an automatic cut-out T to open and disconnect the motor circuit of the car. In order to prevent short circuits taking place, owing to the chains touching the cross-rails at the time they are in contact with the adjacent studs, the studs on each side of each cross-rail are split into two halves in their vertical length, which halves are bridged by a resistance.

The collection generally by the car chains from the studs is steady so long as the weather is of a uniform character. Owing, however, to the fact that the galvanised iron-wire rope, on which the chain links are threaded, has to be fitted with a rope core for flexibility, some difficulty is experienced at times of

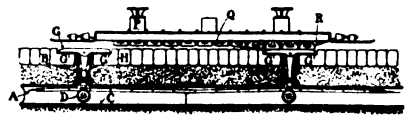

FIG. 2.—STUDS AND COLLECTOR.

change from dry weather to wet through the chain gradually tightening up, with a resultant spitting. But it is intended when next making up any chains to have the lengths of galvanised iron wire boiled in paraffin wax, or linseed oil, in order, if possible, to make the cores non-absorbent.

When designing the actual electromagnets on the car collection equipments, the company found that they could reduce the excitation watts from the 480 specified in the agreement to 260, which has since been reduced, in practice, to 210.

During the first year the total electricity taken gave an average of 1·219 units per car-mile run, or a saving of 0·1185 units per car-mile on the figures guaranteed by the company. During the last eighteen months the consumption has been gradually reduced, and for the year ending March, 1908, was 1·108 units per car-mile.

The line leakage figures during the whole of the time the tramways have been running have been very constant, and have not averaged more than ·25 amperes for the 3 miles of track.

In a clause of the agreement the possibility of studs becoming alive through gradual deterioration while they were not being used for supplying energy to the cars was provided for, the principal reason being that at that time the Lincoln Tramways' Committee rather distrusted the springs, on which the whole responsibility rests of deadening the studs when the car has passed. This fear has turned out to be absolutely groundless, as, during the whole of the time the system has been running, there has never been a live stud which has come under this clause.

There is a kind of temporarily live stud which has apparently given considerable trouble on the Bow Road tramway of the London County Council by remaining alive long enough to be notified by the detector brushes, but which, by the time the car has been reversed and the detector brush again brought over it, has gone dead.

The only time that the author has been troubled with studs coming under this heading was during the severe snowstorm early in January, 1907, when salt was used, without orders, by the roadmen for the purpose of melting the snow.

Below are given some particulars of the live studs during the period of the agreement, and at other intervals, and the effect produced by the different improvements, which have been made from time to time.

Broken Flexibles.—Early in the year a number of live studs were found to have the flexibles broken, and either the spring burnt through or sufficiently elongated to allow the carbon to be in contact with the cable. When the spring had actually parted, it was due to arcing, caused by the current jumping from the broken flexible into the spring, and so out to the head of the stud and the cars. Where

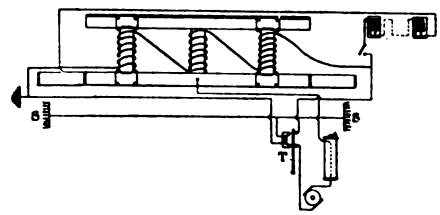

FIG. 3.—DIAGRAM OF CONNECTIONS.

the spring had only elongated there had evidently been better contact established between itself and the flexibles. Investigation revealed the fact that the small copper wires of which the flexibles were composed were being gradually converted into copper carbonate and hydrate, owing to accumulations of gas in the conduit. This trouble was got over by coating the flexibles with a preservative compound, and improving the ventilation of the conduit. For this purpose a Root's blower was installed at the car-shed, and it is the practice to ventilate the conduits for at least half an hour a day before the cars go out, ventilating outlets being placed at three points on the line.

Carbon Burnt on One Side.—This type of live stud was due entirely to the fact that during laying certain of the tee-pieces were not set absolutely vertical. The shape of the carbon which was first installed made no provision for such an eventuality, but on the fault revealing itself a new shape of carbon was

Digitized by Google

brought out which was later installed throughout the line, and trouble from this cause entirely ceased.

Broken Springs.—Of seven studs coming under this head, one was due, not to the breaking of the spring, but to the fact that the hook at the bottom, which holds up the moving armature or switch-piece of the stud operating the carbon contact, was not sufficiently cupped, the consequence being that through continuous working the switch-piece slipped off. The failure of the remaining six springs was due in every case to the same reason, viz., that when the workmen were forming the hook of the springs, in some cases pliers with sharp edges were used and the wire was slightly nicked, and the subsequent working of the stud eventually caused this weakened part of the spring to give way. Other causes of live studs included sticking caused by a blow with a hammer and loose carbons, but since the date of the renewal of the carbons there have only been two instances, and these were found to be due to faulty fixing. There has been no case of studs becoming alive due to leakage from the live cable to the stud.

The author then mentioned the bad wearing qualities of the first form of stranded cable used, and how this had been got over by the adoption of the type of cable now used, which was first put down experimentally over a short section and later installed throughout. The body of the new cable consisted of a galvanised iron stranded wire, 44/0·104 in. wound on to a rope core; the overall diameter was reduced, however, by ¼ in. to allow for the original diameter being made up by afterwards threading on solid drawn galvanised steel tube; for convenience, this latter was put on in lengths of 6 in., which also preserved to the cable the necessary amount of flexibility.

This form of cable was adopted on the grounds that if by wear or bad shorting a hole were burnt through the sleeving, no inconvenience whatever would result, as the cable could at any time be moved, or the sleeve turned slightly round, to give a new bearing. Further, the smooth surface of the sleeves would considerably extend the life of the carbons by obviating the scoring which had previously taken place on the stranded cable; also, the life of the cable itself would be prolonged almost indefinitely, as new sleeves could be threaded on at such time as the original ones had ceased to be of service.

Another item of construction on the track which calls for mention is the stud heads. Those which were installed at the beginning, and which are still in use, are plain cast-iron; though they have stood the traffic very well, they are now slightly hollowed out in the middle, and it has recently been necessary to go through the track packing them up, This operation should make them last for at least another eighteen months or two years, making their total life five years. Despite the fact that over a portion of the line there is a large amount of steam lorry and other heavy traffic, the number of stud heads which have been broken have not amounted during the three years to more than three dozen, and if steel heads were used wherever there was most traffic their breaking would be entirely avoided.

Referring again to the question of live-stud replacements: at Lincoln, owing to the fact that the present length of route is only 1¾ miles, this operation is very easy, and, taking an average position on the line, no more than half an hour need elapse between the notification of a live stud by the car detector and its complete replacement. Two to three minutes only is required to take the stud up after the arrival of the linesman. Every car carries a tripod and lamp, which, in the event of a stud being notified, is placed over it in the road until such time as the linesman arrives; meanwhile, the conductor of each succeeding car removes it and replaces it, so that no inconvenience whatever is caused to the service, especially seeing that during this last few months, since which time the new cable has been installed throughout the track, live studs have not averaged more than about one a month.

Turning to the special equipment required for the cars, no serious difficulty has been experienced. It has been found necessary, on account of the amount of scrap iron—of which ladies' hairpins form a not inconsiderable portion—to be found along the route, to case the iron parts of the collector in wood. The collector chain now used has given great satisfaction, as over 20,000 car-miles is obtained from the cast-iron links which form the units of the chain, and from 8,000 to 10,000 miles as an average life of the galvanised iron-wire rope on which they are threaded.

Having dealt with the special points of the "G.B." system, the author proceeded to contrast it with the overhead system. It must at once be admitted that the "G.B.." system is not as cheap to install as the overhead; but in those towns where there is objection to the overhead wires, it does not seem that 10 per cent. on the cost—the amount by which the "G.B." system exceeds the cost of the overhead—is a large amount to pay.

The Lincoln tramways compare favourably in their maintenance costs with those on the overhead system. For the first complete twelve months' working—viz., up to March 31st, 1907—the total working costs were 6·698d. per car-mile, made us as follows:—

	d.
Traffic expenses	2·512
Repairs and maintenance	0·913
Management and general expenses... ...	1·476
Power expenses	1·797
	6·698

which were reduced for the year ending March 31st, 1908, to 6·10d. per car-mile, made up as follows:—

	d.
Traffic expenses	2·28
Repairs and maintenance	1·25
Management and general expenses	1·18
Power expenses	1·39
	6·10

The average total working costs of some seventy other municipalities, mostly 1907 figures, was 6·31d. per car-mile run, showing an advantage for Lincoln of 0·21d., which, considering the fact that only 145,235 car-miles were run—the fewest of any municipal system—proves to the author that better results might be looked for with a larger system.

With regard to reliability, the author considers that he can claim the advantage. During the whole time the tramways have been running, the current has never been off any part of the line owing to failure of the electrical equipment (apart from the feeders), a claim which the author considers few overhead systems can make. On this account, also, it would be interesting to mention that, apart from the great snowstorm in January, 1907, a total of only 100 car-miles (or 0·022 per cent. of the total car-miles run) have been lost in the three years; in all cases of this total 75 per cent. was due to faults on the cars, and 25 per cent. to the melting out of the main feeder from its socket in the section pillar.

The author considers that, with the working of the "G.B." surface-contact system, there is less danger to the public, from shock and personal injury, than there would be with the overhead system, as studs which have become alive at Lincoln have always been located as soon as they have occurred, without danger to anyone; whereas with the overhead system it is quite possible for a wire to break without giving any warning that inspection could safeguard against. The silent running of the cars at Lincoln is a point which is remarked on by everyone.

DISCUSSION.

Mr. F. HIRD said that the principal point upon which he wished to speak was in respect of the cost of maintenance. It was somewhat of a surprise to hear that the cost of maintenance of the G.B. system compared so favourably with that of the overhead tramways. In fact, it was even a little less than the maintenance cost of many overhead lines. Taking the results obtained at Lincoln as a whole, there was good reason to be astonished at them, but perhaps the cause of this was that in the past the cost of maintenance of overhead lines had been under-estimated and that of the surface-contact system over-estimated. The same might be said of the risks of failure with regard to the two systems. He thought they could take it from the Paper that in this system they had a really successful surface-contact system, and one which, perhaps, if it had come at a little earlier period in the history of electric traction, might have had a very big future. Nevertheless, it must be agreed that it had the advantage of sightliness, and in that respect it might command some field for its application. It would be interesting to see whether a surface-contact system could not be adopted on the city portions of the line, returning to the overhead system in the outer districts. Perhaps Mr. Clegg would say in his reply whether this was feasible without causing any inconvenience or delay in running.

Mr. H. M. SAYERS said that not many years ago he had been asked for an opinion upon surface-contact systems, and had prepared a memorandum stating that in his opinion there was no commercial future for such systems; that in the circumstances which precluded the use of a trolley wire, the conduit system was preferable, and if the amenities of a town and the beauties of its prospects were to be protected and were worth protecting, then it was really worth while to go to the expense of the conduit system. That view was adopted at Bournemouth, where the conduit system had been adopted for the centre of the town and the overhead system for the other parts. When he committed himself to this opinion the only surface-contact system in use in this country—he was not quite sure whether it was really in use or only under construction—was the Lorain system at Wolverhampton, the cost of which was nearly comparable with that of the conduit system. It was worth men-

Digitized by Google

tioning, however, that the Wolverhampton Corporation did not pay this heavy cost, and that the favourable financial results there were largely due to the fact that the Corporation obtained the system at a cost very much below what the contractors had to pay for it. The G.B. system differed from every other that had been suggested or tried by reason of its extreme simplicity, which he thought was the simplicity of genius. The capital expenditure was low on account of its simplicity, and it was evident from the Paper that the working expenses were also low, largely due to simplicity It was a most excellent result that on this line of only about three miles of track they should have been able to work at such a low expenditure as 6·1d. per car-mile. There were one or two points about the G.B. system which must seem doubtful to anyone examining its design. One was the use of the open conduit containing the line wire. Everyone who had had to put wires under streets of towns knew that the atmosphere in such conduits was largely composed of coal gas, and it was obvious that where a certain amount of electric sparking was bound to take place, there was some little risk of explosion, and a constant risk of corrosion of metallic parts. The Paper showed that the corrosion risk, at any rate, had been realised, and that a certain amount of damage had been done, although it also appeared that the danger had been to a large extent overcome. The question of explosion, however, must still remain as a possible risk. Perhaps in Lincoln the soil was not so saturated with gas as in other cities, and the surface of the streets might be more permeable than in London or elsewhere. Again, it must be easier to effectively ventilate 1¾ miles of road by means of a fan or pressure blower than a very great network of conduits. It appeared to him that if this system was used on a large scale under unfavourable conditions it would be found necessary either to abandon the open conduit for the line conductor, or sectionalise it so that the ventilation might be protected and any explosion limited in extent. Another consequence of the open conduit was that the cable was too much exposed to damp as well as gas, and therefore exposed to corrosion. The cable was, in fact, a wearing part, and Mr. Clegg had shown in his Paper that the first cables put in had been very nearly worn out. The new cable was a compound cable as regards conductor. It was a compound of copper and galvanised iron, and it seemed to be a very likely combination to suffer seriously from corrosion if there was any large amount of damp. With regard to the use of sleeves and the suggestion for putting on new ones and moving the whole cable on, it might be possible to do this, but he could imagine that after the sleeves had been in use for two or three years, it might be difficult to move them in this way, or even to get a new contact by rotating them. Another little point was the conductivity as between the cable and the contact sleeves. It was quite possible for a little oxide to form, and to create a good deal of resistance between them. The fact that the cable was a wearing part assimilated this system to the trolley system, but he thought there was a good deal of difference between the ratio of the original value of the cable to its scrap value and the ratio in the case of trolley wire. With regard to current consumption, he gathered that the cars were of the four-wheel type, weighing 9½ or 10 tons, with special radial trucks. He did not know what the gradients were at Lincoln, and so could not accurately compare the current consumption under similar trolley conditions, but 1·1 unit per car-mile was not excessive if the line was an average one. He noticed that the pitch of the studs was 9 ft., and he was certainly surprised that it had been found possible to work with such a long pitch with radial truck cars. The question of the number of studs required per mile of track was a most important one, and every foot added to the pitch helped to remove the great handicap to the use of these systems. It was rather surprising that satisfactory contact could be made with the small magnetic force available, and it was also surprising that the current taken by a tramcar at 500 volts could be satisfactorily broken or shared by such a small break on such a small contact surface.

Mr. J. W. HAME (City Electrical Engineer, York) said he did not wish to enter into the merits of the system compared with others, but merely wished to ask one or two questions. With regard to live studs, it had occurred to him that, supposing the car was at a terminus and the two studs underneath were inoperative, was there any means for the driver to tell whether this was due to a failure of the supply or to the studs themselves? He would also like to know whether the author had found it possible in practice to slide the sleeves along the cable.

Mr. B. H. BEDELL (G.B. Surface-Contact Co.) preferred to answer the criticisms of previous speakers than to deal with the Paper itself. Mr. Sayers anticipated trouble by electrolysis between the copper wires of the cable and the iron wires outside. This would undoubtedly be the case if the copper wires were bare, but owing to the fact that they were tinned there was very little danger of this taking place. Another point raised by Mr. Sayers was that on the car leaving one stud and passing to another the stud that was being left had to share the current with the one in front on to which it was moving, and presumably eventually break its share of the current at the last stud passing under the car. Such a circumstance could not arise in practice, because the carbons were held in contact with the cable until the collector on the car had left the stud. Therefore if there was to be any breaking of circuit at all it must be on the road surface, between the side of the road and the collector. It could not take place between the carbon contact and the cable. If this were not the fact, the life of the carbon would be decreased by something like one-tenth of what it actually was. He entirely agreed with the suggestion that it was necessary to ventilate the conduit thoroughly, but the difficulties which Mr. Sayers pointed out were not met with in practice. A good air circulation could be obtained over some miles, and even if it necessitated the installation of more than one Root's blower it would not be an expensive matter. With regard to the difficulties anticipated in fixing the sleeves, this was very easily done by extracting the cable altogether, which were laid in lengths of about 140 yards. By the aid of a screwed sleeve at the end it was quite possible to push the sleeves along the entire length.

Mr. A. P. TROTTER (Electrical Adviser to the Board of Trade) said that when Mr. Bedell first brought his drawings to be examined at the Board of Trade he confessed that he could not understand how the magnetic circuit was going to work, and how the moving part of the stud was going to be induced to go down on to the cable. The Paper described what might be said to be a most interesting experiment, for although it was a practical working success, yet it must be remembered that the line was a dead level, with small cars, and generally an eminently suitable case for an experiment. Nevertheless, he hoped that it would be copied elsewhere under very different conditions. The inspection of surface-contact systems, from the point of view of public safety, was a rather peculiar duty, for the reason that there was so little to be seen. In fact, whilst everything went well on an inspection, there was nothing to see at all. Consequently they issued provisional certificates for six months. The most important feature, perhaps, of the live-stud question at Lincoln was that everyone of them had been detected by the car. Upon the surface-contact systems in use a few years ago in Paris they used a short-circuiting piece at the back of the car. Mr. Bedell, however, had not such an apparatus. He had an indicating device on the car which gave a warning. A similar device, which rang a bell, was on the Wolverhampton cars at the time of the Board of Trade inspection. When he saw Mr. Bedell's indicating device he asked Mr. Shawfield, of Wolverhampton, how the one there had been working. He was informed that it had been taken off the cars three days after the inspection. The reason for this was interesting. At Wolverhampton the studs were in boxes with thick oil, and consequently they sometimes worked rather sluggishly, and although the studs might be in good working order, if the car was going fast enough the indicating device would come upon the stud before the proper time and indicate a "live" stud, which would, a few seconds later, be found to be dead. He was afterwards told that the method now employed at Wolverhampton for discovering live studs was to pay the barefooted boys which were common in Wolverhampton a penny for reporting a live stud. Then he found that live studs at Wolverhampton were not at 500 volts, but only at about 20–40 volts. This arose almost entirely from the carbonisation of the inside of the top of the boxes, which gave a high resistance circuit, which the Wolverhampton boy could stand. With the G.B. system, however, if the stud was alive it was at 500 volts, but so far live studs had not been a serious matter. On the question of leakage, it was clear that Mr. Clegg was a long way within the limits of the regulations. The most important features of this system were the flush stud and the flexible chain. The question of economy was rather outside his scope, and he had not gone into it. But he must say that the units per car-mile seemed to be very satisfactory. The only other remark he had to make was with regard to Mr. Sayers's description of the conduit as "open." It was, in fact, practically an air-tight tube buried in the ground.

Prof. SILVANUS P. THOMPSON, F.R.S., said that the stud was the starting point of the invention, and presented an extremely beautiful solution to a scientific problem, and embodied a most interesting piece of magnetic mechanism He said this with the greater pleasure because it so happened that the last time that the Institution discussed anything about surface-contact tramways was the occasion when he and Mr. Miles Walker read a Paper about a system with which they had been experimenting at Willesden. He had been through the mill, and had invented two or three different kinds of surface-contact systems, and found nobody who thought they were worth putting any money into; therefore he was the more delighted to welcome this invention, which had turned out to be commercially better than anything of the sort yet put forward. They should not forget that it was now a quarter of a century since Ayrton and Perry proposed a sort of surface-contact system for railways where the moving car was to make contact with studs below or at the side, which were to act for the supply of electricity, and also at the same time to provide an automatic absolute block system. This was followed by other inventions, which led to that extraordinary collection of systems in Paris, including the Clarel Villeumier, Diatto and Dolter;

Digitized by Google

and anyone who had seen the systems at Torquay, Wolverhampton, and Lincoln could have no doubt whatever that the G.B. system was a very great advance on any of them. At Torquay, the drivers of carts kept off the track owing to the mechanical inequalities of the road due to the studs projecting above the surface, but at Lincoln the studs were flush with the road surface. The chain collector was the device which permitted of this, and it was in itself a very great advance. At Torquay they kept two men for detecting live studs by means of a piece of apparatus, although he had been assured that it was very seldom that live studs were found. On this question of live studs, Prof. Thompson said the public had been grossly misled by the extremely unfair and improper device of communications in the Press, headed "The Live-Stud System." There was no such system. They might as well call the overhead system, "The Deadly Trolley System," because horses had been killed by falling wires. It was the general custom to compare this system with the overhead system. But the real comparison should be made with the conduit system, because in places where the surface-contact system was desired, the overhead system would not be tolerated at any cost. Consequently, the rival was the conduit system. This latter was enormously expensive; there were great troubles with dirt and drainage, and at the crossings. In addition, the conduit system involved excavations from 18 in. to 2 ft. 2 in. deep, whereas with the G.B. system it was only necessary to excavate for a very few inches. It had also great advantages in regard to snow compared with the conduit and even the overhead systems. Again, it would be possible to run a combination of the surface-contact and trolley systems without stopping the cars. He hoped there was a great future for surface-contact systems. Any of them who had visited certain towns which they knew in their youth must have deplored the curse that had fallen upon them. Were there any who remembered that lovely square in front of the Cathedral in the ancient city of Milan; it was now one vast spider's web, where the tramcars ran underneath, and the beauty of the Cathedral was to a large extent marred, and the same was true of a great many historical places. Would they care to see Oxford, his birthplace, disfigured by overhead wires, or York, Edinburgh, or Cambridge? Certainly not those of them who had any love for the beautiful left. If they must have electric propulsion of cars, choose between the conduit and surface-contact systems; after what they had heard that evening he did not think any of them would have any doubt whatever as to what their choice would be.

Mr. C. P. SPARKS (who was in the chair in the absence of the President, Mr. W. M. Mordey), read the following letter which had been received by the Secretary from Mr. A. L. C. Fell, Chief Officer of Tramways to the London County Council, and Mr. J. H. Rider, Electrical Engineer to the L.C.C. Tramways.

"We have received your favour of the 5th, asking us to take part in the discussion on the G.B. surface-contact system. It must be obvious to members of the Institution that in consequence of our official position and the fact that the whole question of the G.B. system is more or less *sub judice* at the present time so far as the London County Council is concerned, we are not able to make any remarks whatever upon the subject. In order that our silence may not be misunderstood, we ask that this letter may be read at the meeting."

Mr. STANLEY CLEGG, in reply, said that Mr. Sayers had mentioned that the surface of the roadway in Lincoln might be more porous than that in other places, thus allowing any gas in the soil to get away freely, and thus there would not be a danger of it percolating into the conduits. As a matter of fact, over practically the whole length of track the surface of the road was tar macadam, and as illustrating how this holds anything in the ground he mentioned that recently one of the water mains burst, and the water forced its way into the pipe before it had had time to burst the surface of the roadway open. The cars were not stopped through this, but it caused an anxious time, until it was got rid of. With regard to the sleeves, his idea was to move the whole length of cable a few inches and not the sleeves themselves, in order to obtain a fresh bearing place. At the same time, experience had shown that the sleeves did not stick, for the experimental length of cable had been taken up after 15 months and the sleeves could be turned round quite easily. With regard to the conductivity between the sleeves and the cable, the point where the carbon made contact was immediately above the insulator, which supported the weight of the cable, and therefore the whole weight of that portion of the cable being on the insulator they were bound to get a good contact between the sleeve and the cable. At present there were no apparatus on the cars for showing whether a dead stud was due to a failure of the supply or defects in the stud. But they were so seldom troubled with these that they had not gone into the matter. He would bring the record of live studs up-to-date in the *Journal* of the Institution, but he might mention that the results were as good during the first quarter, if not better, than those previously. The only undetected live stud was during the experiments with the system, and then unfortunately a pony was on it; but the pony was still alive. With regard to Dr. Thompson's remarks as to the true comparison being between the surface-contact and conduit systems, he was afraid that Lincoln would not have had tramways at all if their only option was the conduit system.

IMPROVEMENT OF POWER FACTOR IN ALTERNATING-CURRENT SYSTEMS

A PAPER dealing with the various methods of improving the power factor in alternating-current systems was read on Tuesday, January 12th, by Mr. Miles Walker, of the British Westinghouse Electric and Manufacturing Company, Ltd., before the Manchester Local Section of the Institution of Electrical Engineers. The author points out that a low power factor limits the output of the generators by demagnetising the field magnets and causing heating of the windings. Many generators, particularly turbo-generators, have their output limited by the capacity of their field magnets; and if we regard the capacity of the field magnet only, we will find that the output at unity power factor is four times as great as at 0·8 power-factor lagging. Often the great overload capacity of the steam turbine and armature cannot be utilised, because the lagging current begins to wipe out the field at heavy loads, and it is necessary to start up additional plant. The losses and the inductive drop in the mains are also increased by a low power factor; thus a line wire having only 4 per cent. reactive drop at unity power factor will have 18 per cent. drop at 0·8 power factor.

All classes of alternating-current apparatus require an alternating field for their operation, and a lagging current is required to produce that field. The higher the frequency of the supply, the greater the wattless component. If the field can be produced by a rotating magnet, excited by continuous current, no wattless component is necessary. Indeed, by supplying more continuous-current turns than are necessary, it is possible to create a leading current, which will compensate for a lagging current in another part of the system. The field current of an alternator may be said to have two functions:—(1) To produce the field which generates the E.M.F. in the generator itself; and (2) to supply an additional M.M.F., which, by means of a wattless current, is communicated to all the machines on the system which have not got continuous-current excitation themselves. If we are to reduce the wattless current, we must either use machinery requiring weak magnetic fields, or we must provide independent means of magnetising the fields. A modern transformer does not take a large wattless component in proportion to its output, owing to the excellence of the magnetic circuit. An induction motor, however, having necessarily an air-gap and coils with considerable magnetic leakage, requires a wattless component of 25 to 30 per cent. of the kilovolt-ampere rating. The only other offender of importance is the arc lamp, which produces a lagging current for a different reason.

Synchronous motors have frequently been employed to provide a leading current to compensate for the lagging current taken by other apparatus. Wherever the synchronous motor can have its power utilised, this plan is a good one, but if there is no use for the driving power, the synchronous motor must be regarded as a rather extravagant method for compensating for a lagging current. It is interesting to note that it requires much less wattless kilovolt-amperes to improve a power factor from 0·8 to 0·9 than to improve it from 0·9 to unity. If the power factor of a system is $\cos \phi$, the wattless component is $\sin \phi$, thus the wattless component on a power factor 0·8 is 0·6, and the wattless component on a 0·9 power factor is 0·44, the difference being only 0·16. It therefore takes nearly four times as great a wattless component to change the power factor from 0·8 to unity as it takes to change it from 0·8 to 0·9.

The rotary converter has a great advantage over the synchronous motor-generator set in its high efficiency and greater synchronising power on heavy overloads, and a comparatively small increase in copper weight enables a rotary to supply a leading wattless component equal to 50 per cent. of its kilovolt-ampere rating. In traction systems employing rotary converters, the power factor can be easily maintained at unity, or even

Digitized by Google

made leading, and this enables cheaper turbo-generators to be employed than would be possible with ordinary induction motor converting machinery.

High-voltage condensers have not come into general use for improving power factor owing to their large cost. The result of a long course of experiments on high-voltage condensers made by the Westinghouse Company of America, was to show that while oil-cooled condensers for 40,000 to 60,000 volts could be made on a practical scale, there was no chance of competing with synchronous machinery either in cost or reliability.

As stated above, the reason that the induction motor calls for so large a wattless current is that its magnetising current is supplied at a high frequency. Where, however, the magnetising current is supplied in the rotor at low frequency, the wattless energy required is reduced to 2 or 3 per cent. of that required

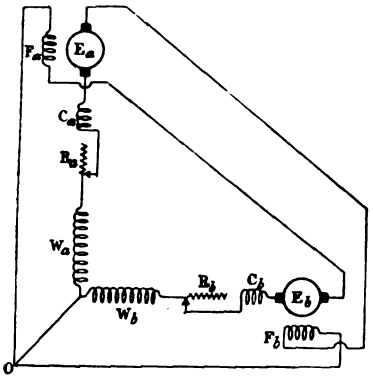

FIG. 1.—CONNECTIONS FOR TWO-PHASE ROTOR WITH LEBLANC'S EXCITERS.

at the frequency of supply. In 1895 M. Leblanc proposed to supply the magnetising current to the rotors of induction motors and generators by means of special exciters, which consisted of commutating alternating-current generators whose magnets were excited by the rotor currents. The method can be most easily followed when applied to a rotor wound for two phases. In Fig. 1 W_a and W_b represent the windings in two phases of the rotor. E_a and E_b are the armatures of the two exciters. These exciters would be made like single-phase series motors, provided with compensating windings. The current from the phase W_a passes from the collector ring through the compensating winding C_a through the armature E_a and then through the field F_b of the exciter in phase B, and thence to the neutral point O. The current from phase W_b passes through the compensating winding C_b through the armature E_b and then through the field F_a of the exciter in phase A and to the neutral point. The induction motor can be started up by means of the resistances R_a R_b, the exciters being short-circuited. When the motor is running, the armature E_a has generated in it an E.M.F. which is in phase with the current in phase B, and if the polarity of the poles is properly arranged, this E.M.F. will be leading 90° on the current in phase A. Similarly the armature E_b can be made to supply an E.M.F. whose phase would lead by 90° on the current in phase B. This has the effect of making the currents in the rotor take up a phase in advance of the E.M.F. produced in the rotor; so that not only can the magnetic field of the induction motor be created by the rotor currents, but the current in the stator can be made to lead on the E.M.F. of the supply. By increasing the speed of the exciters, the E.M.F. at right angles to the current can be increased, and the lead of the rotor current increased more and more. It will be seen, however, that with the connections made as shown in Fig. 1, the more the rotor current leads, the greater is the component of the exciter E.M.F. opposing the E.M.F. generated in the rotor circuit, and this has the effect of increasing the slip of the motor.

If Leblanc's exciters, as described by him in 1895, were applied to a three-phase rotor, three exciters would be necessary, and it would be possible to excite each exciter by currents from all three phases in a great number of combinations. The main point in view would always be to generate in each circuit an E.M.F. which has a large component at right angles to the E.M.F. generated by the rotor slip. Some tests were made by the British Westinghouse Company to see how far Leblanc's method could be carried out commercially. A 170-h.p. 25-cycle induction motor, whose rotor was wound in three phases, generating 600 volts when locked, was belted to a direct-current generator as a convenient means of loading. The brushes on the rotor collector rings were connected in series with the armatures of ordinary direct-current series crane motors driven as series generators. When the motor was running the frequency was too small to cause any trouble with the commutation. With the motor on full load, and 90 per cent. power factor, it was found that as the exciters gradually increased in speed, the power factor first increased, then became slightly leading. With the speed of the exciter kept constant at such a value as to give unity power factor on quarter load, it was found that very little change occurred in the power factor up to half load. As the load was further increased the power factor first became slightly leading and then fell back to unity, and at full load it was 0·95 lagging. A slight increase in the speed of the exciter brought the power factor to unity at full load, and gave a leading power factor on lighter loads. Readings were taken with the motor running at full load and unity power factor, of the voltages between various points of the exciter circuit, and it was found that the results obtained tallied well with what might be expected from theoretical considerations.

The main objection to this method is that it requires two or three exciters, and as the currents to be dealt with would in general be large, the cost of these exciters becomes excessive. Leblanc has described an exciter which embodies all phases in one machine. The armature is made like an ordinary drum-wound continuous-current armature, which is surrounded by a simple ring of laminations, having inwardly projecting poles, but without any field windings. If a two-pole armature of this kind is provided with four brushes placed at 90° to one another on the commutator and connected to the four slip rings of a two-phase rotor of an induction motor, and is run at a speed which is high as compared with the frequency in the rotor circuits, it will have the effect of producing leading currents in the rotor. The armature currents themselves excite the field, and produce a flux in the armature which is in such a phase as to generate an E.M.F. in each circuit, exactly at right angles to the current carried by that circuit. Whether the E.M.F. leads or lags behind the current, depends only on the direction of rotation. By proper design, and by using carbon brushes, the commutation of such an exciter could be made sufficiently good; but the commutator, say, for a 1,000-h.p. motor, would be of considerable dimensions, and it is probable for this reason that they have not come into use.

Before proceeding to describe a form of exciter developed by himself, the author refers to Heyland's arrangement, in which currents are led into the rotor to magnetise it by means of brushes fed from the external circuit. It is clear that if brushes

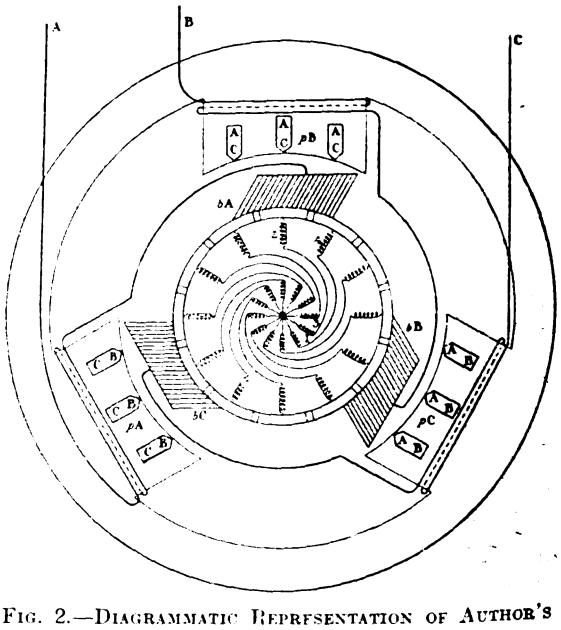

FIG. 2.—DIAGRAMMATIC REPRESENTATION OF AUTHOR'S "PHASE ADVANCER."

are placed upon the end ring of a squirrel-cage rotor, and currents of the frequency n_1 of the supply are fed by means of brushes into the end ring, which is rotating with a frequency n_2, the currents in that ring will have a frequency $n_1 - n_2$—*i.e.*, they will have the same frequency as the slip. If now the ring is of such a resistance that a large proportion of the current passes through the rotor bars on its way from one brush to another, this current can be made to magnetise the rotor if the brushes are rocked into a suitable position. In actual practice it would not be advisable to deal with such a large current as ordinarily flows in the end rings of a squirrel-cage rotor, so that

Digitized by Google

it is necessary to employ a wound rotor and take tappings from this rotor to a suitable commutator. Heyland has developed this motor, and has minimised the sparking on such a commutator by means of resistances connected between the commutator bars. The total cost of the induction motor, however, is considerably increased by the addition of the commutator.

The author then describes his own form of exciter, which, he considers, can be made for a small cost as compared with the induction motor, and would be of practical service in cases where it is important to improve the power factor. The important features to aim at in the design of such a machine, which might be called a "phase-advancer," are :—(1) The commutator and brush gear must not be excessively large; (2) the commutation should be induced rather than be dependent on the resistance of the brushes; (3) it should be possible to control the phase of the E.M.F.'s generated by it, and to decrease rather than increase the slip of the motor; and (4) the "phase-advancer" should be an independent unit, so that in case of its failure the motor could be run as an ordinary induction motor. Fig. 2 gives the diagrammatic representation of such a "phase-advancer." When wound for three phases the field magnet has three poles or any multiple of three. The armature coils are like the coils of an ordinary railway motor, except that they have in the case illustrated in Fig. 2 a span of 120° instead of 90°. One end of each coil is connected to a star-point, and each outer end is connected to one bar of the commutator. On the commutator are three brushes which bear upon the segments connected to coils which are for the time being passing under a pole. Each pole is provided with a compensating winding placed in slots in the pole-face, the winding being arranged so that the ampere-wires per inch along the pole-face are equal, or slightly greater, than the ampere-wires per inch of periphery of the armature. If we follow one of the armature circuits, commencing from the star-point along coil 1, 2, it will pass under the pole *pC*, then under the pole *pB*, and it will make as many turns in front of the poles *pC* and *pB* as are necessary to generate the required voltage. It then passes to brush *bA* and on to the series exciting coil on pole *pA*, then it passes to the compensating windings marked *A* in the slots in poles *pC* and *pB*, and from these to phase *A* of the rotor of the induction motor. The currents in the other phases pass through similar circuits, and it will be seen that the E.M.F. generated in any phase is due to a field which is produced by the current in the other two phases. The effect of the compensating winding, distributed as shown in Fig. 2, is to equalise the current in all the wires passing under one pole. For if the current in any one coil—say 1, 2—is less than the average of all the coils under the pole, the compensating winding in the middle slot strengthens the field in which coil 3, 4 is moving, and strengthens the current in this coil, which in the next instant takes up the position occupied by coil 1, 2. The commutation is induced in the following way :—The brushes are rocked forward until the E.M.F. generated in the coil about to leave the brush is just so much less than the E.M.F. in the coils under the pole that the currents sink to zero before the commutator segment leaves the brush. As the machine is series wound, the field is approximately proportional to the current for the time being, so that theoretically good commutating conditions prevail at all loads. In actual practice, the parts of the brush under the pole can be made of a compressed metal and carbon, which gives a low drop of voltage between brush and commutator, while the part of the brush on which sparkling might occur can be made of carbon. With high conductivity brushes of great breadth, it is possible to employ a smaller commutator than would be possible if the commutation were forced by means of narrower brushes of high resistance.

By the use of an exciter in the rotor circuit it will be possible to greatly increase the output of a motor frame, as rotors can generally stand 10 to 20 per cent. more current without exceeding the temperature guarantees. But a much greater gain in output can be secured by deepening the slots of both stator and rotor and putting in bigger conductors. At present the depth of the slots is limited, because it is so desirable to keep down the leakage flux and the length of saturated teeth. But when the exciting current is supplied to the rotor, the slots in the stator and rotor can be deepened until the leakage flux begins to saturate excessively the rotor iron. The limitations of an induction motor frame will then be similar to those of a synchronous motor frame. The pull-out torque will be very much increased, because not only can the working flux be kept up to its full value, but it is kept more nearly in phase with the stator currents.

It has been shown that if the E.M.F. of the exciter has a considerable component opposed to the E.M.F. generated in the rotor winding, the slip is increased. The exciter can therefore be utilised to change the speed of an induction motor. The exciter, when its E.M.F. is opposed to the rotor E.M.F., runs as a motor, and is capable of putting back into the system the power represented by the slip of the induction motor, which would otherwise be wasted in a resistance. Suppose, for instance, that it is required to change the speed of an induction motor 10 per cent. An exciter like that shown in Fig. 2, but having additional exciting coils, is belted to the induction motor and connected to its slip rings. The pole opposite brush *bA* will be provided with a series coil fed from the brush *bA*, and similarly all the poles will be provided with coils whose polarity is such that an E.M.F. is generated in each branch of the circuit in a direction opposed to the E.M.F. generated in the rotor winding. These coils will be provided with diverters to allow of proper adjustment. If all the current is diverted from these coils the phase-advancer operates without increasing the slip. Then as more and more current is passed through the coils the slip is gradually increased. Meanwhile the phase-advancer develops more and more torque as a motor. The amount of slip which can be produced depends on the output of the phase-advancer and its ability to commutate the currents through it as their frequency increases. It is possible to drive the phase-advancer either by an induction motor or by a direct-current motor, and when acting as a slip augmentor it would drive either of these as generators. Such a combination would be useful where an induction motor is required to drive a flywheel set; the control of the slip augmentor might be made automatic, so as to keep the torque of the induction motor approximately constant notwithstanding the change in the speed of the flywheel. The phase-advancer would at the same time keep the power factor at unity.

This "phase-advancer" may also be employed for exciting the rotor of an induction generator. As is well known, an ordinary induction generator, with short-circuited rotor, though capable of yielding power when supplied with a magnetising current from an alternating-current system, is not capable of relieving any synchronous generators in parallel with it of the wattless component of a lagging load. An induction generator, in fact, adds to the wattless component. If, however, we excite the rotor of an induction generator with a leading current, the armature becomes capable of supplying a wattless component to help any synchronous generators in parallel with it. For example, if a two-phase rotor of an induction turbo-generator is to be excited by means of a "phase-advancer," the rotor and "phase-advancer" are mounted on the same shaft, and one end of each phase of the rotor winding is connected to the shaft. The other ends are connected to slip-rings, and from these rings the current is collected by means of brushes and carried to the brushes of the phase-advancer, which in this case would be provided with four poles. The inner ends of all the armature coils are connected to the shaft, and the operation of the exciter is exactly the same as in the case described in Fig. 2, except that two phases are employed instead of three.

Mr. Miles Walker concluded his Paper as follows :—"An important subject to be discussed by our station engineers is the means which can be employed for inducing consumers to improve their power factor. The rates charged for electrical supply commonly in vogue do not take account of the power factor of the consumer's load. Station engineers, while exercising some control over the character of the motors installed, do not as a rule offer the consumer sufficient inducement to improve his power factor. When we remember that the capital charges (especially for mains) form such a large proportion of the total costs of supplying electricity, and also the small proportion which the cost of coal bears to the total cost, in many cases it would seem to be fairer to charge the consumer by the kilovolt-ampere than to charge him by the kilowatt."

DISCUSSION.

Mr. S. J. WATSON (Engineer-in-Chief, Corporation Electricity Works, Bury), who took the chair as Mr. Miles Walker, the chairman of the section, was the reader of the Paper, opened the discussion. He said that the problem of improving the power factor in alternating-current systems was easily solved in sub-stations by adopting different types of machines, but, on the other hand, there was always a certain inadvisability of mixing synchronous and induction machines in one station. Moreover, the present-day practice tended towards alternating-current distribution, so that there was scope for some such device as Mr. Walker had described. He thought, however, that consumers would object to be charged by ampere-hour meter, as Mr. Walker had suggested, and the question arose who was to supply the device described? Objection arose to charging consumers for units which were not generated. Mr. Watson further pointed out that the motor load was not the only load that gave a lagging current, for metal filament lamp transformers had also a serious effect in this direction. Finally he asked what was the additional cost of the motor with Mr. Walker's supplementary device, and what was the combined

Digitized by Google

efficiency of the motor with the device added? He also asked what was the largest motor in which the Heyland pattern commutator had been employed?

Mr. F. C. RAPHAEL said that he feared there would be some difficulty in inducing consumers to adopt any device which increased the cost of their motors, and which also interfered with the extreme simplicity of the induction motor by adding a commutator arrangement. The consumer at present paid by the units he consumed, consequently he did not mind what was the power factor of his motors. In the case of systems with static sub-stations, the supply authority could not improve the power factor by using synchronous machinery in the sub-stations, but he thought that too much was made of the C^2R losses in the mains due to the wattless currents. C^2R losses were, after all, a comparatively small percentage of the load, and an increase of these losses merely meant increasing the power lost by a percentage of a percentage. He thought, therefore, that attention should be directed to improving the power factor at the station end, and he welcomed Mr. Walker's Paper as giving a very clear exposition of the whole subject, which would doubtless assist people in arriving at the best apparatus to put in at a power station to improve the power factor of the load.

Mr. A. F. GUY (Electric Light and Power Department, G.P.O., Manchester) suggested that if there were sparking difficulties with Mr. Walker's device, air blasts might be added on the commutator as on the Elihu-Thomson arc lighter.

Mr. J. FRITH (Mather & Platt, Ltd.) said that so many people had tried to produce an induction motor with a high power factor, that he could not help thinking someone would really have "happened on" one by now if it were really possible. He could not see the difficulty in making an increased charge for consumers with bad power factors. At present there was nothing to prevent them increasing their air gap and their peace of mind at the expense of the supply authority. Consumers were already penalised for bad load factors; why should they not be educated up to be penalised for bad power factors?

Mr. A. E. MCKENZIE (Resident Engineer, Stuart Street Station, Manchester) said that on the Manchester system they had no great trouble with bad power factor, as they had synchronous machines in their sub-stations. At Stuart Street the power factor was seldom below 0·95. He agreed with Mr. Frith that an extra charge should be made for bad power factors. An official could quite well be sent round to investigate and measure the power factor, and an extra charge could be made when necessary. He agreed with Mr. Raphael that the adjusting device should be placed in the power station.

Mr. C. F. SMITH (Municipal Technical School, Manchester) objected to the term "wattless power," which had been employed not only by Mr. Walker, but even by Steinmetz. Steinmetz in his book had actually referred to "wattless power or powerless volt-amperes," an expression that could only be put into a book by an extraordinary genius or an abject fool, for power could certainly not be described as powerless. Mr. Smith preferred the term "idle power."

Mr. J. S. PECK (British Westinghouse Co.) referred in appreciative terms to Leblanc's ingenuity. Leblanc had invented the motor converter, the use of damping coils, an ice-making machine, a steam condenser, and, long enough ago for his patent to expire, an exciter for improving the power factor for induction motors. The Leblanc machines employed a similar idea to that used in the single-phase railway motor. Things moved in circles in the electrical industry; we had come back to fast speed generators, and perhaps we should also have ampere-hour meters back again.

Mr. W. CRAMP (Municipal School of Technology, Manchester) said that Manchester was "jolly lucky" to have such a high power factor as 0·95. A station he had recently visited in the Midlands had a power factor seldom above 0·72, and sometimes as low as 0·66. In connection with the subject of the Paper, Mr. Cramp referred to the suggestion made in Mr. Swinburne's Presidential address before the Institution of Electrical Engineers in 1902 for an electro-magnetic condenser. Referring to his own work, Mr. Cramp said that in 1903 he had tried to make repulsion motors with wide brushes, and had described them in a Paper before the British Association. He had further found it impossible to keep the commutator cool, and perhaps Mr. Walker would find this more difficult than he contemplated in his device. Mr. Walker had mentioned a composite brush, but he had found that unequal expansion due to the heat caused such a brush (in which two materials were used under pressure) to be badly chipped at the corners. To judge from Mr. Walker's diagrams, he thought that the exciter would have to be a fairly large machine. Finally he said that a machine such as this would be equally applicable at the central station end.

Mr. A. G. COOPER (Engineer-in-Chief, Corporation Electricity Works, Colne) said that he had had much experience with Elihu-Thomson arc lighters, and had found that the brushes wore very quickly, and that there was much trouble with the blowers.

Mr. T. H. SWINBURNE asked what would be the actual economy in capital charges and running expenses by using Mr. Walker's device?

Mr. J. S. PECK, speaking again, said that at the Clyde Valley power station a synchronous motor had been used with success to improve the power factor.

Mr. H. C. CREWS objected to the term "penalising the consumer." The proper way was to give the consumer a concession to induce him to use machinery with a better power factor, and not to penalise him for bad power factors.

Mr. MILES WALKER, replying to some of the points raised in the discussion, said that the cost of the motor and its efficiency were still a matter for experiment. Possibly the motor itself could be made to cost from 20 per cent. to 30 per cent. less than if the device were not used, and its performance would be improved. But this, he feared, would hardly be sufficient to make up for the added cost of the exciter device. Moreover, the efficiency would possibly also be reduced on balance, but depended on the size of the motor. The best device to have in the station to take the wattless component of the energy—he would accept Mr. Smith's suggestion, and not say the wattless power—was to have a large enough alternator to take the wattless current. He pointed out incidentally also that his "phase advancer" could not be expected to take the wattless current at starting, but would only compensate for the low power factor when running.

ELECTRICALLY-CONTROLLED FIRE-BOATS IN CHICAGO

THE two new fire-boats which have recently been put into service in Chicago are interesting from the fact that although steam-driven, electrical transmission is employed. The boats are propelled by twin screws, independently driven by electric motors, which derive current from generators mounted on the shafts of the steam turbines operating the centrifugal fire-pumps. Two controllers, one on each side of the pilot house, govern the screw propellers respectively, and it is found that by this arrangement the whole of the steering can be effected much more rapidly than by the use of the rudder. The steam turbines, centrifugal pumps, and electrical generators are compactly arranged nearly amidships. At each side of the engine-room hold there is a 660-h.p. horizontal Curtis turbine, on the shaft of which is mounted a 5,500-gallon centrifugal pump and a 200 kw., shunt-wound, 275-volt, direct-current generator. In the centre of the engine-room floor is placed the power switchboard, where all the operative connections are made. This board is equipped with circuit-breakers, switches for power and lights, ammeters, voltmeters, &c. Within reach of the engineer's station there are two controllers similar to those in the pilot-house, for the port and starboard screws, respectively, which may be used to control the boat, by throwing in a proper connecting switch on the switchboard. In this case the vessel is steered with the wheel and rudder, the engineer receiving his orders through a speaking-tube which leads from the pilot's station.

Abaft the pump turbines and switchboard, on the engine-room floor, are mounted two 125-volt exciter and lighting sets, of twenty-five kw. capacity each, direct-connected to steam turbines. Either one of these sets is of a capacity sufficient to carry the entire excitation and lighting load.

Almost in the extreme stern, mounted on the propeller shafts, are the large driving motors. These machines are of the variable-speed, reversing type, developing 250 h.p. at 200 revolutions per minute. The motor shafts are direct-connected to the propeller shafts through rigid flange couplings. The propeller motors are controlled and operated at any desired speed by varying the impressed voltage applied to their armatures.

Although the primary reason for adopting electrical transmission may have been to permit of the same turbines being employed for pumping and propulsion, the ease and rapidity with which the boat can be controlled in a crowded waterway has been found far superior to the working of rudders and transmission of orders to the engine-room. There are other important incidental advantages in driving the screws by motors instead of by steam engines. One is that if the boat ever has to go into heavy swells, there is no racing of the screws, the speed of revolution being almost constant for the voltage applied, without regard to the load. It is also possible for short periods to increase the revolutions and power developed by the motors considerably. Another advantage is that a sudden strain put upon the shaft by the propeller striking heavy ice, or running against dock piles or other obstructions which are frequently encountered in the confined spaces in which the boats must operate, means nothing more than throwing out a protective circuit-breaker.

The centrifugal fire-pumps are of the two-stage type, with 14-inch suction and discharge. The two pumps are together capable of furnishing 9,000 gallons of water per minute, at a pressure of 150 pounds per square inch, when running at 1,700 r.p.m. If necessary the two can be coupled in series to deliver 4,500 gallons per minute at 300 lbs. per square inch.

CORRESPONDENCE

ELECTRICAL POWER COMPANIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read with a good deal of interest the article by your "Pessimistic Correspondent" on the prospects of electrical power companies in general, and whilst agreeing with many of his statements as regards mistakes made in the past, must join issue with him as regards the outlook for the future.

The comparative failure of power companies hitherto is primarily due to the difficulties experienced in raising the necessary capital, and where this capital has been found by manufacturers of electrical machinery or cables, the latter have naturally safeguarded themselves by obtaining very high prices for the generating plant and mains supplied to the power company. Moreover, the prices originally asked by power companies were a good deal too high to allow of a rapid development of the use of electrical energy in the areas controlled by them. This was especially the case in regard to the question of bulk supply to municipalities. Many of the smaller municipal undertakings would not now exist as separate generating plants had the power companies in their vicinity been bold enough to offer a bulk supply at a price which it would have paid the municipality to have accepted.

The figures quoted by your correspondent in the case of an imaginary power company are really too extraordinary for anything. The days when "one power-house equipped with 8,000-kilowatt of plant, together with a fair allowance of mains and transforming stations," could cost anything approaching £600,000 have long since departed. An up-to-date power station with four 2,000-kilowatt generating sets should not cost more than £120,000, and a similarly up-to-date system of distribution (at 6,000 volts, three-phase) over a very extensive area should not cost more than £150,000. If a further sum of £30,000 is allowed for Parliamentary and development expenses and for working capital, the total capital of the concern need not exceed £300,000.

As regards the question of depreciation, I should consider an allowance of 4 per cent. amply sufficient if made accumulative on the sinking fund principle. This would require an annual sum of £12,000. Allowing 5 per cent. for interest on capital by way of dividend, a further sum of £15,000 is required. Thus the total annual payments in respect of capital charges amount to £27,000, which, on an output of 16,000,000 units, is equivalent to 0·39d. per unit approximately. If, as your correspondent assumes, the generating station has been erected in a position where there are plentiful supplies of cheap fuel and water, the total works costs should not exceed 0·27d. per unit, and unless conditions are abnormal, the management and general establishment charges should be kept within the figures of 0·1d. per unit. Therefore, the total cost of production may be taken as 0·39d. + 0·27d. + 0·1d. = 0·76d.

The question then becomes: Can a power company obtain an average price of practically ¾d. per unit on an output of some 17,000,000 units? Personally, I do not think there should be any difficulty whatever; and, indeed, I very much doubt whether the average selling price of any power company at present in operation is as low as ¾d. per unit.

Yours faithfully,

C. E. C. SHAWFIELD.

Corporation Electricity Works, Wolverhampton,
January 13th, 1909.

THE REGULATION OF ARC LAMPS WITH "CONVERGING" CARBONS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—After reading your interesting article on the above subject, together with the letters of the able experts thereanent, I feel myself very much in the position of the author of the famous "Snakes in Iceland" in writing you on the same subject! In the Abbey flame lamp exhibited by my company at the recent exhibition at Manchester, there is no "blow magnet." As a matter of fact, with the mechanism employed in our lamp, no such device has been found necessary. It is well to know what means to employ to overcome an existing difficulty, but if that difficulty can be eliminated altogether it is better still, and on this principle may I ask you to find space for these brief remarks in your valuable journal?

Yours faithfully,

H. P. BLECKLY.

The Abbey Electric Co., London,
January 15th, 1909.

CONDUIT WIRING

A PAPER was read on Friday last by Mr. L. M. Waterhouse before the Scottish Section of the Electrical Contractors' Association, on conduit wiring. The author defined the function of a metal conduit system as being to provide the necessary protective channels through the building to enable the conductors to be drawn in, and when in to be protected throughout their entire length from mechanical, chemical, or electrolytic damage arising either externally or internally. He gave it as his opinion that the requirements were best met by iron suitably protected from corrosion, and quoted statements by fire office engineers in support of this. A description was then given of the different varieties of iron conduit in use. Heavy gauge conduits are made from rolled strip, with the edges brazed or welded. Seamless or solid drawn conduits are in some ways more satisfactory, but much more costly.

In welded conduit, the heat necessary to produce an efficient weld is naturally high, and in the process, unless scrupulous care is taken, scale is formed, and impurities and foreign matter are taken up, leaving the tube in a rough condition, with the possibility of internal burrs and fins, which are naturally fatal to electric cables, and which burrs and fins, moreover, are difficult to remove by "rodding." Moreover, such welded tubes rarely have the accurate diameter which is possessed by brazed and solid drawn. The welded conduit manufactured by the Simplex Co. goes under the name of "Wireduct," to distinguish it from the welded material of the gas-barrel variety. Here, in addition to the ordinary welding process, "Wireduct," while still at a high temperature, has a bulb-ended mandril forced through it, and it also goes through a pair of sizing rolls to ensure both the accuracy of its dimensions, and to give it a smooth surface, free from all internal obstructions.

Brazed conduit possesses certain advantages over the welded variety in that the temperature necessary for uniting its edges is low compared with the temperature required to affect a welded junction, and if the brazing has been successfully accomplished, and the tube thoroughly rodded to remove any spelter that may have penetrated inside, we have a tube produced that makes a satisfactory conduit with an invariably smooth diameter, possessing a smooth surface, and absolutely straight.

Mr. Waterhouse then referred to the advisability of continuity and earthing, but considered that they did not form a complete safeguard against fire risk unless contact with gas pipes is guarded against. An earthing conductor of small sectional area is possibly all that is required to minimise the risk to person from shock or burn, but it must be borne in mind that a fault on a sub-main may only be protected by a fuse many times too large to prevent the earthing wire from dangerously overheating, and for this reason the earthing wires should be of ample sectional area.

Mr. Lackie, Chief Electrical Engineer, Glasgow Corporation, has recommended entire insulation of conduit runs. This might be desirable if practicable at reasonable expense. Some figures

Digitized by Google

of electrical fires in Glasgow were quoted, which had been put forward by Mr. Lackie to support the contention that continuity and earthing are not an absolute safeguard against fire.

The troubles due to condensation of moisture had been greatly exaggerated, but he was inclined to think that the actual amount of condensation if confined to its own particular length of tube is of negligible effect.

In the majority of cases where water has lodged in tubes to any extent or fallen down into receptacles such as the well-glasses of watertight fittings, or iron switch boxes, it is in connection with what may be termed special installations—bleach or dye works, cold storage works, or in very exposed situations, or rooms subjected to extraordinary variations of temperature, and here, again, the accumulation of water at any one spot, which is usually a vulnerable one, is due to the draining of a considerable length of conduit.

The suggestions he put forward for avoiding condensation troubles where these are to be feared were:—The efficient draining of all vertical conduit runs and dips; the blocking of all outlets inside junction boxes, and inspection fittings, to prevent the free circulation of air; the use of a sufficiently high-grade cable, and special care in handling it from the time it arrives on the job; the careful finishing off of all connections wherever the cable is cut; the blocking of all conduits at least ¾ in. from all walls.

After some notes on the mounting of switches, ceiling roses, &c., the question of the qualities of a suitable enamel for conduit tube was considered, and results of tests were quoted to show the excellence of the material employed by the Simplex

The materials requisite for the equipment of a conduit installation on the most satisfactory lines were summarised as follows:—A flexible stranded copper cable of high conductivity, where the necessary flexibility is secured by obtaining the required cross sectional by employing a large number of relatively small wires; a dielectric of pure and vulcanised rubber of high and lasting insulation properties, but of such a thickness which shall not unduly increase the diameter of the cable. A conduit of even diameter and smooth bore of ample size for drawing through the various circuits, made electrically and mechanically continuous by means of screwed threads, and having sufficient thickness of wall to take the standard thread without unduly weakening it mechanically. The material should further lend itself to reasonable bending; but, on the other hand, it should not be soft enough to allow the penetration of a nail. Fittings and accessories of malleable iron, designed for the reception and drawing through of cables, with smooth interiors and watertight covers. These fittings should be distributed at convenient points to admit of drawing through the circuits without difficulty. The exercise of scrupulous care in the drawing through of all circuits. The efficient protection of cables at all places where there is a possibility of damage to their insulation covering by the free use of nipples and bell mouth-pieces. The proper fixing of all conduit runs on their supports, and the rimering of all conduits whenever they are cut.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published To-day

The publication of the specifications announced for January 14th, a list of which appeared in our last issue, has been postponed until to-day. No specifications were published on January 14th.

Application for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of Jan. 13th, 1909.

374 of 1906. **Thermal Switch.** An application for the amendment of this specification has been made by W. V. D. KELLEY. The switch consists of two fixed metal strips inclined to each other, and secured together at one end. A heating coil is arranged on one leg, and this is intermittently short-circuited by the movement caused by the expansion of the heated leg. Lamps in series with the switch are dimmed when the heating coil is in circuit, but burn bright when the coil is short-circuited. The advantage of the switch is that the circuit is never opened. References to means of breaking the circuit are made in the specification, and it is desired to delete these references.

Expiring Patents

The following patents expire during the current week after a life of fourteen years:—

1,611 of January 23rd, 1895. **Train Lighting and Heating.** E. J. PRESTON and A. B. GILL. This specification relates to a system of lighting and heating for railway carriages and other vehicles, in which the dynamo is driven from a carriage axle by means of a slipping belt. A reversing switch controlled by a centrifugal governor, a variable resistance for automatically regulating the pressure across the lamps, and means for automatically controlling the lubrication, are described.

1,731 of January 24th, 1895. **Storage Battery Plates.** C. A. FAURE and F. KING. A plate for storage batteries, which consists of a light conducting support for the active material covered with silicated asbestos fabric, and finally encased in perforated celluloid or ebonite, is described in this specification.

PETROL-ELECTRIC OMNIBUS SYSTEMS

AT the Society of Road Traction Engineers on Monday a discussion upon the relative advantages of petrol-electric and gear transmission for omnibuses was opened by Mr. W. A. Stevens, of Maidstone, whose petrol-electric system is used in an omnibus now being run by Messrs. Tillings (see ELECTRICAL ENGINEERING, Vol. III., p. 83). Mr. Stevens proposed the following resolution:—"That electric transmission from the engine to the road wheels is preferable to other forms of transmission for the same purpose." It was originally intended that Mr. George Pollard, of the London General Omnibus Co., should have followed Mr. Stevens on behalf of other forms of transmission, but he was prevented from attending, and Mr. A. W. Windsor, who took his place, was only asked to do so in the meeting room, and was consequently unprepared with any figures.

Mr. W. A. STEVENS, in introducing the subject of the debate, said that he did not propose to recapitulate the various petrol-electric systems. This had already been dealt with in Papers read in January, 1907, by Messrs. Hart and Durtnall, and in March, 1908, by Mr. P. H. Frost Smith, and himself (ELECTRICAL ENGINEERING, Vol. I., pp. 147 and 267, and Vol. III., p. 475). His object was to deal with electrical transmission generally as opposed to purely gear-driven systems, especially with reference to its advantages in connection with public service vehicles. In advocating any new system of transmission it was necessary to show that it possessed tangible advantages which appealed to the shareholders and the engineers as well as to the general public. To the former, low maintenance and running costs, reasonable first costs and freedom from police stops were the dominant factors. With the latter, silence, smoothness of running, and, if possible, little or no smell from the products of combustion. From the point of view of the public, the purely electric omnibus was the ideal vehicle, and when the problem of battery maintenance at a low cost was successfully solved (and there were indications that important advances in this direction were being made), it would hold the field in towns where a supply of electrical energy for charging purposes could be obtained at a cost of 1d. per unit or less. The problem was not only to produce a vehicle which would show low running and maintenance costs in the first year, but to put a vehicle on the road which at the end of five years, or seven years, would be as efficient and silent in its running as at the end of the first year, at a minimum cost for upkeep. It had been contended that electric motors could not be made sufficiently robust to stand the racket and strain of omnibus work. This, he was pleased to say, was not his experience. In the Hallford Stevens petrol-electric vehicle, with S. B. and S. worm-drive, in the service of Messrs. Thomas Tilling, Ltd., which had run 35,000 miles in public service in 49 weeks, the electric motors had not required repairs of any description for the last 28,000 miles, the brushes had not been renewed, and the motors were now in as good condition as when they were new. With the best possible electrical transmission, however,

Digitized by Google

the vehicle as a whole must be a failure if the final (or mechanical) drive was inefficient, noisy, or would not stand up to its work. In the particular vehicle he was interested in, the electric motors were mounted on the frame, each driving a road wheel by means of a single reduction worm gear, a dog clutch on the worm-wheel engaging with a similar clutch on the road wheel, this latter running on a floating bush on the dead axle. This form of mechanical transmission had already been described in the Paper of last March already referred to, and he was pleased to say the results anticipated therein, in the year's (or rather 49 weeks), running of 34,891 miles, averaging 714 per week, had been fully realised, and it might be of interest to compare the estimated working costs given in that Paper with the actual results of working for the six months ending December 31st, 1908, which, by the kind permission of the directors of Messrs. Thomas Tilling, Ltd., he was able to give, together with the average costs of the remainder of the fleet, all gear-driven vehicles.

WORKING COSTS, PENCE PER MILE.

	Petrol-Electric.	Gear-driven. Average.
Running	0·875d.	1·607d.
Maintenance	0·082d.	1·169d.
Tyres	1·500d.	1·500d.
Drivers	1·245d.	1·245d.
Conductors	0·897d.	0·897d.
Petrol	1·220d.	1·089d.
Lubricants	0·067d.	0·286d.
Grease	0·005d.	0·066d.
Paraffin	0·050d.	0·050d.
Vehicle lighting	0·134d.	0·136d.
Body upkeep	0·320d.	0·324d.
Traffic expenses—Insurance, rent, rates and taxes, water, gas, &c., supervision, depreciations, telephones, establishment charges, &c.	2·125d.	1·737d.
	8·520d.	10·106d.

These figures, which were official and could be confirmed, showed a balance in favour of the petrol-electric vehicle of 1·586d. per mile, this on an average running of 35,000 miles per annum, representing a saving of £230 per annum on each vehicle. In a fleet of 500 vehicles the saving would be at least £115,000 per annum.

The great saving in running costs and maintenance, viz., 1·819d. per mile, was due to the place of the clutch, gear box, and differential, with either internal rack, chain wheels and chains, or worm gear, as the case may be, as a final drive, being taken by a dynamo, controller, and two electric motors driving single reduction worm gears, and it was upon the durability of its transmission that the petrol-electric based its claim to existence. After a run of 35,000 miles the single reduction worm drives showed so little signs of wear, that the life of a set of worms and worm-wheels could be set down at 100,000 miles, and the maintenance of this part of the transmission might be taken at no more than 0·2d. per mile. He also estimated a run of 35,000 miles without renewing the brushes on the motors. The gear-driven vehicles had scored during the past six months to the extent of 0·131d. per mile in regard to petrol, but the cause of this has been found, and in the future, especially in new vehicles, the figures would be on a par, with a possible advantage to the petrol-electric. Lubricants and grease, however, reversed the position, showing an advantage to the petrol-electric of 0·28d. per mile, giving to the petrol-electric a net advantage on petrol, lubricants, and grease of 0·15d. per mile. The combined items, traffic expenses, insurance, rent, rates and taxes, water, gas, supervision, depreciation, telephones, establishment charges, &c., counted against the petrol-electric to the amount of 0·388d. owing to the cost of the chassis of the petrol-electric vehicle being 25 per cent. more than that of the gear-driven, and also to its being subject to only a year's depreciation. As, however, the life of the petrol-electric must be at least 25 per cent. longer than that of the gear-driven, this difference might be ignored. With the advent of the electrically propelled vehicle, whether of the petrol-electric or purely electric variety, the possibilities of silent running would be fully demonstrated, and it was quite possible that London might eventually follow the lead of Brighton and refuse to give licences to gear-driven omnibuses, unless on the understanding that they would be replaced as early as possible by vehicles of a silent-running type.

From the drivers' point of view, the petrol-electric, with its simple control, powerful brakes, and flexibility in traffic, had a great advantage over the gear-driven omnibus, with its nerve-racking gear changes after every stop. He had confined his comparisons of cost with that of gear-driven petrol vehicles, as he had no figures of the running costs of steam omnibuses. The weight of the chassis of the Tilling omnibus was 3 tons 3 cwt., and the total weight 4 tons 13 cwt.

Mr. A. W. WINDSOR pointed out that although the figures quoted by Mr. Stevens were very remarkable—and he admitted that he had none in regard to gear-driven vehicles to put against these—at any rate, in regard to the cost of petrol, the gear-driven 'buses were a long way ahead. Generally, of course, the petrol-electric system scored, which was what one would expect, because certain of the components had been done away with. He did not quite see, however, why the body upkeep should be lower with petrol-electric. The last item on the list was also in favour of the gear-driven vehicles, due, he supposed, to the high rate of depreciation on the higher original cost. The advocates of petrol-electric systems always presupposed that their maintenance troubles disappeared, but the greatest trouble of all, viz., the engine, still remained. He would like to know if electric braking was practicable, in order to do away with mechanical brakes. Acceleration might be a good feature for omnibuses, but it was open to question whether this was entirely an advantage, especially in London. Personally he knew instances in which the slowest 'buses in regard to acceleration picked up more passengers. On this question he mentioned that steam 'buses were quite equal to the petrol-electric, and showed as even an acceleration curve. The acceleration of the Electrobus was very even, but the 'buses were very slow. He was rather afraid that petrol-electric 'buses would require more skilled mechanics for their repair than was the case with gear-driven vehicles. Summing up, he said that on the question of noise, undoubtedly the petrol-electric scored, although a great deal of the trouble in this direction with other types of omnibus was caused by the action of the police. At the same time, whilst admitting that some of the petrol omnibuses were heathenish in their noises a few years ago, enormous improvements had been made in the meantime, and many of them now ran as silently as could be wished. In the matter of capital expenditure, the petrol-electric system compared very unfavourably. Mr. Stevens had mentioned the mental strain upon the driver with the present types, but he thought this was very much overdone, an opinion which he had come to after the experience of having some 500 drivers pass through his hands. These certainly did not seem to be the class of men to be troubled with nervous disorders. He would like to have some more particulars of the gear-driven vehicles, the costs of which Mr. Stevens had compared with his petrol-electric 'bus, because Mr. Searle, of the London General Omnibus Co., had, at another meeting recently, mentioned the figure of 8¾d. per car mile, so it would appear that Mr. Stevens's figures for this type of vehicle was not a good average. It was also a fact that the cost of upkeep of many of the older 'buses was gradually going down. In conclusion, he thought it was questionable whether the advantages gained by the petrol-electric system warranted the extra expenditure involved, because he could not get his mind away from the fact that there were still a gear-driven axle and an engine.

Mr. KENT THOMAS (Messrs. J. & E. Hall, Ltd.) said that even though higher-paid men were necessary for repair work on petrol-electric omnibuses, the amount of repair work necessary was enormously less, and allowed of fewer men to do the work. His experience was that the worst thing that could happen was a burnt-out armature, and this not very often. Further, to repair petrol-electric omnibuses, it was not necessary to pull the chassis to pieces to anything like the same extent as was the case with gear-driven vehicles.

Mr. W. WORBY BEAUMONT asked how old the petrol omnibuses were with which Mr. Stevens had made his comparisons. He thought they were a great deal older than the petrol-electric vehicles; in fact, he might almost call them ancient in motor-omnibus history. He also would like more information about prime cost. The extra weight in a petrol-electric omnibus had a considerable effect upon the cost and running upkeep, although there were distinct advantages from the electric drive.

Col. R. E. CROMPTON, C.B., said that although he was interested in steam omnibuses, yet, after fully considering the matter, he had come to the conclusion that Mr. Stevens had proved his case. Electrical machinery was incomparably simpler than any other class, its complexity being in its design and not in its working or maintenance. With regard to repair work he was sorry, as a manufacturer, to say that this was becoming almost a negligible quantity, as he knew of machines 25 years old which had hardly been repaired at all. For this reason it was not necessary to have highly skilled men for repair work; in fact, he regretted to see the large number of young men now being turned out in the electrical industry who were being paid extraordinarily low rates of wages for this work. This showed that the work was not of a very high order. He contended that it was only due to the great skill of the engineers of omnibus companies that the petrol vehicles had been kept on the streets as long as they had. The Electrobus was the best of all, if, and it was a very big if, the accumulators could be maintained at the prices mentioned by the Electrobus Company. With regard to Mr. Stevens's omnibus, he was quite prepared to see him obtain better results in the second year of running than in the first, owing to the 'bus having got into its proper stride. In the comparison made by Mr. Stevens, he thought they could really strike out the question of depreciation, for whereas on the one hand it was based on the higher price of the petrol-electric, on the other hand it was based on the largely

Digitized by Google

written down price of the petrol 'buses. Further, depreciation of electrical machinery was at an incomparably lower rate than other forms of machinery, as manufacturers of electrical machinery knew to their cost. It was surprising to see the success with which the Electrobus had met in spite of its bad coach work, which he likened to the red trains on the Inner Circle. Personally, his opinion was that if the Electrobus had not come to stay, then it would be a close fight between steam and petrol-electric, with the gear drive nowhere; in fact, he predicted the gear-driven petrol omnibus would be in the museum in about two years' time.

Mr. THOMPSON LYON asked if Mr. Stevens could give some figures as to the cost of running the Electrobus, as up to now he had been unable to obtain any figures which were at all conclusive.

Mr. P. FROST SMITH (Messrs. Tilling Bros.) said that, having had charge of the petrol-electric 'bus mentioned by Mr. Stevens, he would answer one or two questions on matters which had not come directly under Mr. Stevens's notice. With regard to depreciation, the directors of Messrs. Tilling had taken seven years as the period in both cases, and an equal number of miles each year for the vehicles. He did not wish to give the rate of depreciation allowed, but at the same time he thought that, with the lower rate of depreciation on the electrical system, another three years could well be added to its life. It was astonishing how little repairs had to be done to the electrical equipment; in fact, the vehicles had run 28,000 miles without any repairs at all. The petrol-electric 'bus had run 49 weeks with police stop notices on two minor matters, but nothing whatever to do with the equipment. He rather regarded the 8¾d. mentioned by Mr. Windsor as fiction, having in mind the 300 omnibuses which that company had laid by, and not in service. Although the petrol vehicles which had been compared with the petrol-electric omnibus were three years old, they had all been reconstructed, and at the beginning of 1907 he considered they were in better condition than they were when they were first delivered new.

Mr. W. A. STEVENS, in reply, called attention to the fact that although the engine was still retained, it had continuous smooth running, and was not continually pulled up, as in the gear system. Electric brakes were risky, and it was not thought advisable to put them in the hands of an ordinary driver, especially as the mechanical brakes were quite efficient. It was practically impossible for a burn-out to occur now on the motors, because the dynamo was limited by the power of the engine and the motors were capable of taking twice the output of the dynamo. On the question of repairs, he mentioned that he had had a petrol-electric light car which had run 10,000 miles with only one stop, and that not in connection with the electrical machinery. At the commencement it was found that one motor was pulling and the other was being pulled, but they balanced the motors by having a differential voltmeter. The two motors were in series, one coil of the voltmeter being across one armature and the other coil across the other armature. They then weakened one field by shunting it until the needle of the differential voltmeter came to zero, when the vehicle was running forward. Therefore they had the same voltage across each armature. With regard to the upkeep of battery omnibuses, he was supplying some electric omnibuses to the Brighton & Hove Omnibus Co., and it could be taken generally that the total costs were about 1s. per car mile in London, and about 1s. 1d. per car mile elsewhere, owing to the extra cost of battery maintenance. These particular omnibuses were being converted from petrol omnibuses.

LOCAL NOTES

ASHBY-DE-LA-ZOUCH: *Electric Lighting.*—Owing to the unsatisfactory gas supply, the Finance Committee has recommended that the cost of an electric supply scheme be inquired into, and that the services of a consulting engineer be engaged for the purpose. Whilst the question of immediate action has been held over for a month, the suggestion has been made that a supply might be taken from the power station of the Midland Railway Co. at Swadlincote, which supplies the Burton-Ashby light electric railway.

BARROW-IN-FURNESS: *Heavy Tramway Damages.*—The British Electric Traction Co. have agreed to pay a cyclist, who was injured in a collision with one of the tramcars in Barrow, the sum of £525 as damages.

BATH: *Sale of Electricity Undertaking.*—A deputation of the Corporation waited upon the Board of Trade on Thursday with regard to its refusal to sanction the purchase of the Corporation electricity works by a syndicate, for whom Mr. Schenk is acting. The interview was private, and, pending a further interview with Mr. Schenk, the Corporation have decided not to make any statement.

BRISTOL: *Opposition to Somerset Power Co.*—The Corporation is opposing the Bill of the Somerset & District Electric Power Co., on Standing Orders. It is alleged that proper notice of the Bill was not given in the *London Gazette* in November, the notice not being published until December 18th, the statutory date being November 27th. It is further alleged that the notice, when published, was erroneous and misleading.

BRUMBY AND FRODINGHAM: *Provisional Order Revoked.*—The Board of Trade have revoked the electric lighting Provisional Order granted to the Council in 1903.

CANADA: *Ontario Power Co.*—It is stated that the Ontario Power Co. intends to increase its output by 65,000 h.p., at a cost of £160,000, in order to supply power to fourteen municipalities in the province of Ontario. An American Consular report gives the information that under the terms of its charter the Ontario Power Co. may develop 180,000 h.p. At the present time it is developing 75,000 h.p. When the contemplated additions are completed the plant will be in position to deliver 140,000 h.p. By the ruling of the War Department the Ontario Power Co. may export to the United States 60,000 h.p., while at the present time but 30,000 is being exported.

Ontario Power Transmission.—It is announced that 44 municipalities in Ontario have been offered a supply of electric power from the Government transmission line, which is now being erected. A vote on the answer to be given to this offer is to be taken at the same time as the municipal elections.

DARLINGTON: *The Trackless Trolley System.*—The Electricity and Light Railways Committee has had under consideration the construction of the tramway extension to Haughton-le-Skerne, for which powers are already possessed. The Town Clerk and the Borough Surveyor have been instructed to draw up a report on the matter, the points to be considered being whether an extension of time for carrying out the Order should be asked for, whether a single or double line should be laid, and whether the trackless trolley system should be adopted.

DEVONPORT: *The Tramways Company.*—The Tramways Committee have reported upon the intimation of the Devonport & District Tramways Co. to discontinue running cars upon certain of the leased lines (ELECTRICAL ENGINEERING, December 31st, p. 848). It was pointed out that the action of the company would certainly cause very great inconvenience to the public, and affect an expenditure of £60,000, the cost of the construction of the track and its equipment. The lines in question were leased to the company for the residue of a term of 28 years from 1898 to 1926. Under that lease the company paid interest on sinking fund, road rentals, and a contribution towards the Camel's Head bridge improvement, which made a total of £3,896 per annum. On March 10th, 1908, a letter was sent to the Town Clerk complaining that the lines were unremunerative, and making two proposals. The first was that there should be a sliding scale for a reduction in the price of current, but that reduction was to apply not only to the leased lines, but to their own lines as well, and the sliding scale was to continue for five years. Assuming that the amount of current used was the same as that used until March, 1908, it would mean a loss to the Corporation in electricity alone of £6,149; in five years afterwards an annual loss of £1,845 per annum. A proposal was made for the reduction of other charges, which in five years would represent a loss of £2,240 and an annual reduction of £448. It really meant that for the first five years there would be a loss of £8,389, and afterwards an annual loss of £2,293. Those proposals were very drastic. The committee went into the matter, and they thought the proposals so extreme that they were never brought before the Council. The second proposal of the company was that the company were prepared to negotiate for the sale of their tramways under the Tramways Act of 1870, which really meant that they would sell the undertaking under agreement, and not under compulsory powers. Their reply to that was that the Corporation would probably consider any proposal for the sale of the undertaking, but to that they had had no response. No fresh proposals had been received until December 17th, when the notice to discontinue the working of the lines on and after January 16th was received. The committee had been well advised as to the legal aspect, and were acting on that advice in the steps they had taken. If the service was discontinued, serious as it was to the many who would be affected, the report concluded that it would be more serious to the company, and the company would be wise to reconsider the matter and put some reasonable proposal before the Council.

DUBLIN: *Heavy Tramway Damages.*—A carter named George Leudrum, aged 64, was awarded £350 against the Dublin United Tramways Co. last week for injuries received through a tramcar colliding with the rear of his trolley and making the horses bolt. He was thrown off the vehicle and seriously injured.

DUNDEE: *The Trackless Trolley System.*—A proposal has been made that the trackless trolley system be installed along the Esplanade. Three cars would be required, and the estimated cost of the installation was put at £5,000. It has been decided to appoint a committee consisting of a representative of each ward to consider the matter and to report.

HANLEY: *Electricity Staff Dinner.*—The fifth annual dinner of the electricity works staff was held at the "Lion" Hotel, Victoria Square, Shelton, on Thursday, January 7th, 1909, when there was a large gathering of the staff and friends.

Digitized by Google

HEYWOOD: *The Tramways Undertaking.*—The Bill which has been deposited giving extended powers in relation to the municipal tramways undertaking, has been confirmed by resolutions passed in the Council. Negotiations have been in progress with the Bury Corporation for an agreement for running powers into Bury and Rochdale, but no terms have been arrived at, and as the Bury Corporation are promoting a Bill seeking running powers into Heywood and Rochdale, the Council has decided to oppose this.

HYTHE: *The Tramways Bill.*—A special meeting of the General Purposes Committee is to be held to consider the Bill deposited by the National Electric Construction Co., by which they seek to install the overhead system instead of the surface-contact system as provided by the company's original Act of Parliament.

ILFORD: *The Tramways Undertaking.*—Mr. A. H. Shaw, the Electrical Engineer and Tramways Manager, has reported upon the tramway undertaking, dealing specially with recent criticisms passed upon it. The Engineer admitted that the current consumption per car mile had increased since the first year of the undertaking, but this was, he added, by no means peculiar to Ilford, having been experienced by the majority of other undertakings, including Manchester, Sheffield, and Leeds. With regard to the fact that 1½d. per unit of electricity was charged to tramways, whereas manufacturers were charged 1d., it was only large consumers who used motors for running their works, and who had to reach a certain minimum each quarter, who were charged 1d., and at the present time only two customers got current at this rate. He considered the price, 1½d., was too low, and did not pay the electricity department, and rather than the electricity department being subsidised by the tramways, as had been insinuated, he was of opinion that the reverse was the case. The Engineer denies that the cars had been neglected and allowed to get into a very bad condition. He also pointed out that the annual balance commenced to fall off long before he took over the management. Although the undertaking was not in as good a condition as one would wish to see it, he did not consider it was in anything like such a deplorable condition as the public had recently been led to believe, and it was certainly in a much more healthy condition than very many municipal undertakings throughout the country. In conclusion, the Engineer said if the Council were satisfied with his work in connection with the undertaking and wished him to continue in his present position, there were certain matters which he would be glad to have considered before long, and upon which he proposed presenting a report at an early date. Otherwise, he would be pleased to revert to the position he held prior to July, 1906, viz., Electrical Engineer only. The question of the future management of the undertaking and the Engineer's salary has been referred to a special meeting of the Council in committee.

Tramway Intercommunication.—The Barking Council has suggested a conference between Sir Herbert Jekyll, of the Board of Trade, and representatives of Ilford and Barking, to settle the question of the inter-running of cars on the two tramway systems, but the Ilford Council have replied that in their opinion no good purpose would be served by such a conference.

INDIA: *Industrial Development.*—The American Consul in Calcutta has forwarded the following information relative to the industrial development of British India, having received a number of letters from American manufacturers of electrical machinery about the chances of making sales of their goods in India. He states that the value of electrical machinery and goods shipped into Bengal during 1906–7 was $613,516; into Bombay, $266,496; into Sind, $47,536; and into Burma, $282,240; other provinces helping to make up a grand total of $1,858,924. Of this, it is claimed that the British manufacturers furnished $375,457, and the bulk of the balance, $1,483,467, went to the United States. He concludes that the electrical machinery made in the United States is considered by electrical engineers as the best made in the world, and the same is true of electrical supplies.

LINCOLN: *Tramway Employees Supper.*—In order that all the tramway employees may meet together once a year, the idea of a midnight meal was conceived last year, and the function proved very successful. The second of the series was held last week, when some 70 persons sat down, the concert which followed being continued until it was time to commence work the following morning.

LITTLE HULTON: *Electric Lighting Order.*—The Board of Trade having intimated to the Council that their electric lighting Provisional Order was expiring, a communication was sent to the Lancashire Electric Power Co., who have promised to take over the Order. The company, in reply, stated that during the last few weeks a large sum of money had been raised to develop their business, and steps were being taken to remove every possible objection the Board of Trade might have to their taking over the Orders of the authorities with whom they had been in negotiation. They were in close touch with the Board, and expected to learn in a short time that they were prepared to favourably consider the question of the transfers.

LIVERPOOL: *The Trackless Trolley System.*—At a ratepayers' meeting on Monday, the clause in the Liverpool Corporation Bill which has been deposited in Parliament for next session, empowering the use of the trackless trolley system, was opposed on behalf of the Liverpool Cart Owners' Association, and was defeated by a large majority. A poll will now be taken.

LONDON: *London County Council: Tramways.*—It is anticipated that the link between the northern and southern tramway systems of the London County Council at Harlesden and Putney will be opened for traffic this week. Through cars will not be run, however, until some widenings are carried out at Hammersmith Broadway. Work has been commenced upon the horse tramways from Vauxhall to East Hill, *via* Lavender Hill, the cars having been withdrawn completely during the process of converting the line to electric traction.

A carman named Page was awarded £100 damages against the County Council at the Westminster County Court, on Monday, for injuries received in a collision between his vehicle and a tramcar in Caledonian Road, Islington.

Islington: Street Boxes.—The Parliamentary and General Purposes Committee call attention to the fact that no provision is made in the L.C.C.'s General Powers Bill for next session, for removing small street boxes in the public way from the operation of the London Building Act, although until a recent decision of the Divisional Court in the case of Perkins *v.* The County of London Electric Supply Co., it was never contemplated that district surveyors could claim annual fees in respect of such boxes. A petition under the seal of the Islington Council is to be deposited against the Bill in order to secure a *locus.*

Marylebone: Street Lighting.—A recommendation by the Electric Supply Committee to apply for a loan of £8,000 for the conversion of 1,964 street gas lamps into electric lamps, has been adopted by the Council. We gave full details of the scheme in ELECTRICAL ENGINEERING, Vol. IV., p. 724.

Metropolitan Asylums Board: Electric Lighting.—Some time ago a report was called for dealing generally with the results of the substitution of electric light for gas in some of their institutions. The Hospitals Committee reported that from the point of view of the effect upon the health of patients and staff, the sanitary aspect, convenience and comfort, safety from fire, economy in cleansing, and the cost of maintenance, electricity was far superior to gas. Acting on this report, other institutions were given electric installations, and the Board's Finance Committee has now drawn up a further report, stating that they are satisfied that the substitution of electricity for gas has been generally economical.

Shoreditch: "Linking up."—A conference of representatives of the Metropolitan Borough Councils possessing electricity undertakings was held a few days ago in the Town Hall, when the question of putting the recently passed Electric Supply Act into force was considered. Mr. Vorley (Islington) argued that it would be premature to meet the companies, as suggested, before the municipalities knew exactly what the linking-up would cost, and other particulars. He accordingly moved a resolution to the effect that a scheme of linking-up be formulated before the municipalities entered into consultation with the companies. This was finally agreed to.

MANCHESTER: *Overhead Wires.*—The four committees concerned in the overhead wire question, referred to on page 48 of our last issue, held a conference on Thursday. The meeting was adjourned until to-day.

The Trackless Trolley System.—The Manchester Ratepayers' Association is opposed to the powers sought in the Corporation Bill for next session for the adoption of the trackless trolley system. These powers, it is claimed, are being sought on the strength of a report of a committee which visited the Continent, which did not contain an engineer, consisting only of three laymen and the general manager of the tramways undertaking. It is urged that as not one of the large German cities will adopt the system, Manchester should not go into the matter without further detailed investigation. At a meeting of the ratepayers on Tuesday, the clause was defeated by a small majority.

MIDDLESEX: *Tramways.*—In consequence of the opposition to the introduction of tramways at Muswell Hill, the Light Railways Committee of the County Council have reported against the scheme.

NAIRN (N.B.): *Electric Lighting.*—The Board of Trade has asked what steps are being taken to put the Council's electric lighting Order into effect. The Council has approached a number of companies in the matter, but has failed to secure their co-operation, and the Board of Trade, in having the facts put before them, are to be asked for an extension of time.

NEATH: *Electric Supply.*—The Local Government Board has sanctioned a loan of £17,000 for the purchase of the local power station from the South Wales Electrical Power Distribution Co. The Council, however, have further applied for a loan of £11,000 for extensions of the undertaking, but this has not yet been sanctioned.

NOTTINGHAM: *Tramway Workers Social.*—The third annual social concert and dance of the Nottingham Branch of the Amalgamated Association of Tramway and Vehicle Workers was held last week, some 200 persons being present.

Digitized by Google

NUNEATON: *The Cost of Meters.*—The Local Government Board has intimated to the Council that in future meters must be paid for out of revenue. The Council has written to the Board protesting against this.

OLDHAM: *Supply Outside Area.*—The Lancashire Electric Power Co. are opposing, at the Standing Orders stage, the Bill of the Corporation, one of the clauses of which relates to supply outside the borough. The ground of this early stage opposition is that the objects of this and other clauses were not disclosed in the statutory notices.

PONTYPRIDD: *Municipal Issue.*—An issue of £207,150 3½ per cent. redeemable stock at 95½ is being made for the purposes of the various undertakings of the Corporation, including the electricity supply undertaking.

RICHMOND: *Tramways.*—The Council are to oppose the London United Tramways Bill, which seeks to empower the company to use the overhead trolley system in the Kew Road. Under previous Acts of Parliament and agreements with the Council, the system to be adopted was to be approved by the Council, and it was further stipulated that the overhead system should not be used.

RIO DE JANEIRO: *The Tramway Dispute.*—The Rio de Janeiro Tramway, Light & Power Co. in London has received a cablegram stating that the reports of the riots and disorders in Rio are very much exaggerated. The disturbances did not arise from an increase in fares, as reported, but from a temporary discontinuance of certain lines for the purpose of reconstruction of the track in the Largo San Francisco. The disturbances were of no significance, and no damage of any importance to the company's cars was done.

SALFORD: *Tramways.*—The estimates of the proposed expenditure under the provisions of the "omnibus" Bill which has been deposited for next session, show that £60,000 will be expended on the tramways undertaking.

SOUTH AFRICA: *Pietermaritzburg Loan.*—Subscriptions have been invited during the week for an issue of £200,000 4 per cent. consolidated stock at 92½. The issue is for the purpose of providing money for completion of the water supply and sewerage schemes, and also to provide £110,000 for defraying the cost of extending the electric supply and tramways undertaking.

STOCKPORT: *Lease of Tramways.*—Notice is given of the intention of the Corporation to lease what are known as the Wellington Roads and St. Peter's Gate tramway and the Daw Bank tramway to the Manchester Corporation. The rents reserved will be as follows:—As to the Wellington Roads and St. Peter's Gate tramway, £4,596 6s. 9d. for the period between June 1st, 1902, and December 1st, 1907, and afterwards £1,030 7s. 4d. per annum (except the last half-year of the term, the rent for which is £515 4s. 3d.). As to the Daw Bank tramway, £485 6s. 10d. for the period between January 23rd, 1903, and December 1st, 1907, and afterwards £100 per annum.

TAUNTON: *Condition of Tramway Track.*—The Tramways Company, who had had their attention called to the condition of the tramway track have replied that they will give this matter attention in the future as in the past. The Corporation have regarded this communication as of a somewhat flippant nature, and have given the company two months' notice in which to carry out the repairs which they think necessary.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BERMONDSEY.—Electrical mains are to be laid at an estimated cost of: feeder, £1,049; distributor, £373. A further distributor will shortly be laid at an expected cost of £489.

KEIGHLEY.—A loan of £12,820 for additional generating plant has been applied for.

NUNEATON.—The Local Government Board has sanctioned a loan of £2,424 for electricity works extensions.

SOUTHAMPTON.—Tenders are to be invited for the supply of cable, and for four generators.

WATFORD.—The Local Government Board have written, stating that they are not prepared to sanction the whole of the Council's application for a loan for extensions in 1908, but they consented to the sanctioning of a loan of £1,750.

Miscellaneous

AUSTRALIA.—The Board of Trade correspondent at Melbourne has forwarded a copy of the specification, conditions, and drawings relating to the supply and delivery at Toowoomba of a branching multiple magneto switchboard, tenders for which will be received by the Deputy Postmaster-General, Brisbane, up to May 31st. Specifications and tender forms may be obtained and preliminary deposits paid at the Australian Commonwealth Offices in London, 72 Victoria Street, S.W. A copy of the conditions, &c., may be consulted by British makers interested on application at the Commercial Intelligence Branch of the Board of Trade.

AYR.—The tramways are to be extended to Hawkhill. Over a greater portion of the route the double track will be laid, the estimated cost of the extension being £13,614.

BIRMINGHAM.—The Tramways Department require tenders for the supply of the following stores during the year ending 1910:—Bolts and nuts, washers, &c.; brushes (including paint brushes); cotton waste, white rags, sponges, &c.; chemicals, acids, &c.; electrical sundries, ironmongery, files, glass, iron and steel, iron and steel castings, malleable iron castings, oils, greases, &c., paints, varnishes, &c., springs, insulating materials, leather and rubber goods. Particulars from the General Manager, and tenders by February 8th.

LONDON: *Islington.*—The following stores are required for the electricity department during the year ending March 31st, 1910:—Engine-room stores, arc lamp carbons and globes, oil, transformers and accessories, iron, tools, belting, cotton rope, &c., earthenware pipes, troughs, bricks, fire-bricks, fireclay, &c., electricity supply meters and prepayment meters, cables, electrical sundries, lamps, brushes, arc lamp parts, &c., cable, terminal, service, and network boxes, and tapes. Particulars from the Town Clerk, to whom tenders by February 5th.

Metropolitan Asylums Board.—The internal telephone and fire-alarm systems at the South Western Hospital are to be remodelled at an estimated cost of £500.

PLYMOUTH.—Tenders are invited for the following stores for the electricity department during the coming financial year:—Arc lamp carbons, meters, transformers, paper-insulated cables, lubricating oils, engine waste, &c. Particulars from the Borough Electrical Engineer, to whom tenders by January 30th.

SHEFFIELD.—The Tramways Committee require stores during the coming financial year, including car fittings, overhead line fittings, power station supplies, lamps, &c. Particulars from the General Manager, and tenders to the Town Clerk by February 5th.

SPAIN.—*The Board of Trade Journal* states that the "Dirección-General de Obras Públicas," Madrid, requires tenders for the construction and working of an electric tramway from the Paseo de Recoletos to the Calle de la Florida. The concession will be for 60 years. A deposit of 7,481 pesetas (about £267) will be required to qualify. Tenders by March 6th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.E.—Erection of Meeting Hall, Tower Street, Hackney. Builders, T. Gates & Sons, 187 Queen's Road, N.E.

N.—Church, Colney Hatch Lane (£10,000). Architects, Caroe & Passmore, 3 Great College Street, S.W.

Police Station. Surveyor to Metropolitan Police, J. Dixon Butler, New Scotland Yard, S.W.

W.—Erection of buildings for William Whiteley, Ltd., on site of Queen's Road Baths and wash-houses.

Additions to Baptist Chapel, King Street (£1,015). Architects, Gordon Wilson & Co., 667 Fulham Road, S.W.

PROVINCES.

BELFAST.—Addition to Municipal Technical Institute. Architect, Samuel Stevenson, 83 Royal Avenue, Belfast.

BIRMINGHAM.—Factory for Messrs. Mitchell, pen manufacturers. Architects, F. B. Andrews, 95 Colmore Row, Birmingham.

BRISTOL.—Extension, All Saints' Church, Fishpond Street. Architect, E. H. Linger, Barker & Son, 3 Unity Street, College Square, Bristol.

COLCHESTER.—Technical Institute (£10,000). J. H. Nicholas, Secretary, Ecclesiastical Education Committee, Chelmsford.

DARLINGTON.—School (£10,000). G. Winter, Borough Engineer, Town Hall, Darlington.

DEWSBURY.—Music hall on the Manor House Estate (2,000 places). Architects, Chadwick & Watson, Leeds.

DOVER.—Dual school, Maison Dieu Gardens. Sir Wollaston Knocker, Town Clerk, Dover.

DUNDEE.—Tenders are invited for the installation of electric light at the Sanitary Offices, West Bell Street. Particulars from the City Engineer, and tenders to the Town Clerk by January 25th.

EDINBURGH.—Additions, Magdalen Asylum (£2,000). J. A. Carfrae, 3 Queen Street, Edinburgh.

FLINT.—Patent silk factory (£50,000). Architects, Briggs & Wolstenholme, May Buildings, 51 North John Street, Liverpool.

GREENOCK.—Roman Catholic School. Patrick Street (£10,000). Architect, W. R. Watson, 95 Buth Street, Glasgow.

HARROGATE.—Tenders are invited from local contractors for wiring and fitting the following schools, for electric lighting:—Grove Road, Oatlands, Starbeck, and Western. Par-

Digitized by Google

ticulars from the Borough Electrical Engineers, and tenders to the Borough Surveyor by January 26th.

HARROGATE.—Extensions at Royal Baths (£8,850). F. Bagshaw, Borough Engineer.

NEWPORT (I.O.W.).—School. Architect, P. Stone, Holyrood Street, Newport, I.O.W.

SOUTHAMPTON.—Alterations, Assembly Hall, Park Street. Architect, A. A. Burnett, 2 High Street, Southampton.

STAPLE HILL (Bristol).—School. Mr. R. S. Phillips, The Cross, Gloucester.

ST. ALBANS (Herts).—Conversion of Public Library into Higher Education Centre (£2,550). C. E. Longmore, Clerk to the County Council, Hertford.

TORQUAY.—Secondary School (£12,000). H. A. Garrett, Borough Engineer.

TYNEMOUTH.—Y.M.C.A. premises (£5,000). Architect, C. B. Plummer, 13 Grey Street, Newcastle-on-Tyne.

WHITEHAVEN.—School (£10,000). Architects, Oliver & Dodeson, Lowther Street, Carlisle.

WREXHAM.—Church Institute (£4,000). Architects, Prothero & Phillott, Cheltenham.

MISCELLANEOUS CITY NOTES

MEXICAN LIGHT & POWER CO.—It is announced by the Mexico Tramways Co. that the negotiations for a lease of the Mexican Light & Power Co. have been abandoned, and that the offer made by the Tramways Co. has been withdrawn. *The Financier and Bullionist* states that the true significance of the foregoing announcement is that an amalgamation of the two companies' interests has been the subject of negotiation since the abortive meeting of the Mexican Light & Power Co. in Montreal, and that there is every prospect of a successful result. From authoritative sources, our contemporary have received the positive assurance that a settlement has been arrived at between the majority of the Mexican Light & Power Co.'s shareholders and the Mexico Tramways Co. for an amalgamation. The tramways company offer to take over the common shares of the Light & Power Co. on the basis of 14 new shares for every eight now held. Already over 50 per cent. of the common shareholders of the Light & Power Co. have agreed to the terms offered, and the same offer will be made to the other shareholders. Shareholders are now officially advised, by the Canadian Committee, to await the receipt of a circular from them before accepting any arrangement for the exchange of shares.

BRITISH INSULATED & HELSBY CABLES.—The transfer books will be closed from the 18th to the 25th inst., both days inclusive, for the preparation of warrants for dividend on the preference shares. The warrants will be posted on the 30th inst.

MEXICO TRAMWAYS CO.—A dividend of 6 per cent. per annum for the quarter ended December 31st has been announced. Last year the dividend was at the rate of 4 per cent. per annum.

ANGLO-ARGENTINE TRAMWAYS CO.—The scheme of arrangement come to between the Anglo-Argentine Tramways Co. and the 6 per cent. debenture holders of the company was sanctioned in the Chancery Division last week. Under this scheme, for each £100 6 per cent. stock will be issued £155 4 per cent. stock, ranking with the existing 4 per cent. stock.

MONTREAL LIGHT & POWER CO.—A dividend of 1½ per cent., equal to 6 per cent. per annum, has been announced for the quarter to December 31st.

METROPOLITAN RAILWAY CO.—A dividend of ½ per cent. per annum for the half-year to December 31st has been announced. The sum of £17,000 is transferred to electrical renewals and depreciation fund, and £8,700 carried forward.

VICTORIA FALLS POWER CO.—It is announced that the capital of this company is to be increased to £3,500,000, and that an issue will shortly be made of £800,000 5 per cent. debentures and £1,000,000 6 per cent. participating preference shares. It is further stated that with this new capital the company will erect new power stations aggregating over 100,000 h.p.

Telegraph Traffic.—On the 12th instant, private messages for Messina were again admitted, but those for the Province of Messina, Reggio, and Calabria were still subject to sender's risk, while telegrams for other places in Sicily were accepted under normal conditions. The cable between Seattle and Sitka was down on the 13th instant, and messages for Alaska were sent *via* Ashcroft. During the repair of the broken cable between Fort de France (Martinique) and Paramaribo, messages for French and Dutch Guiana will be sent *via* "Salinas." The land lines to Port Limon, Costa Rica, having been restored, communication *via* Mexico is again possible. On the 18th inst., the Malta route to Sicily was again open to general correspondence, which is still subject to delay by the Italian administration. The cable between Djedda and Sonakim ceased operations on the 18th instant. The cable belonging to the West India & Panama Telegraph Co., between Jamaica and Colon, which was interrupted on 8th instant, was successfully repaired on the 18th instant, the break being near Colon.

TENDERS RECEIVED AND ACCEPTED

BRADFORD.—The following tenders for the annual supply of stores have been accepted by the Tramways Department:—Wood & Saberton: Bolts and nuts, carriage bolts, washers, rivets, set screws, miscellaneous ironmongery, round brass rod, nuts. Taylor & Parsons: Nails, brass and iron screws (assorted), coach screws, cotter-pins, gas and steam pipes and fittings (iron), tools, twist drills, wood handles and shafts. Dunlop Rubber Co.: Delivery hose. S. Buckley: Files. General Electric Co.: Lamp fittings, lamps, yellow or white adhesive tape, 1 in. and ½ in. Turners & Manville: P. and B. tape, ½ in. and 1 in. L. Andrew & Co.: Linen frame tape, 1 in. and ¾ in.; bare tinned copper wire, 15s. and 16s. S. W. Whaley & Co.: Egyptian grey tape, sandbags. Brown, Muff & Co.: Calico, wash leathers and sponges, floor cloths. Geo. Cradock & Co.: Strand wire mild steel. H. De Jersey: Iron castings. J. Wells: Malleable castings, steel castings, phosphor bronze castings. Electro Mechanical Brake Co.: Yellow or red metal. Bairstow & Smith: Drivers' alarm bells. Imeson, Finch & Co.: Copper controller contacts. Brecknell, Munro & Rogers: Insulated bolts and strains. Mountain & Gibson: Steel pinions. Cordingley, Armstrong & Co.: Best flat bar iron. A. G. Barrett & Co.: Best round chain iron, best mild flat steel. H. Barrett & Son: Best rod iron, best convex iron, step iron, best mild angle steel; round bright steel. Crossley & Davenport: 1½ in. hex. iron, best hoop iron, best channel iron, best channel steel, best spring steel. S. Peace & Son: Hydraulic steel tube.

DEWSBURY.—The tender of Messrs. Callender's Cable & Construction Co. has been accepted for the supply of 500 yards of 0·025 sq. in. cable.

FELIXSTOWE.—The tender of the General Electric Co. has been accepted for the supply of a 130-kw. Diesel oil-engine generating set at £3,767.

GLASGOW.—The Corporation have accepted the following tenders for the tramways department:—Rolling shutters for Rutherglen sub-station, Mountain & Gibson, Ltd.; oil switches, British Thomson-Houston Co., Ltd.

HULL.—The Tramways Committee were recently put into some difficulty in connection with placing a new order for tramway rails, owing to the fact that the Belgian firm which has hitherto supplied all the rails for Hull can only accept an order for 500 tons, whereas the Tramways Committee only require 200 tons for stock purposes. The Doncaster Corporation has now joined hands with Hull, with the result that an order for 350 tons of rails and accessories has been placed with Messrs. Walter Scott, Ltd., of Leeds, at £7 5s. per ton for rails of the Sandberg quality, as against £6 17s. 6d. by the Belgian firm, and £8 15s. for fish-plates and sole-plates, as against £8 10s. per ton. The comparison is not quite a correct one, however, as there will have to be added to the price charged by the Belgian firm the cost of cartage from the docks, which is estimated at 1s. 11d. per ton.

ICELAND.—Twelve months ago a concession was granted to a Danish syndicate for the establishment of a gas and electricity works at Reykjavik, the capital of Iceland. The company, however, later declared itself unable to make use of the concession unless the Town Council would make certain modifications. This the Council has declared itself unable to do, and an offer by the firm of Karl Franke, of Bremen, to provide the city with an efficient lighting service, to be completed next autumn, has been accepted. The city has the option of purchasing the undertaking one year after completion.

MAIDSTONE.—The following tenders have been received for the supply of cable for the supply of cable from the electricity works to the Allington sewage works:—Western Electric Co. (accepted), £904; British Insulated & Helsby Cables, £936; W. T. Henley's Telegraph Works Co., £929; Callender's Cable & Construction Co., £916; W. T. Glover & Co., £913; Johnson & Phillips, £912.

SOUTHAMPTON.—The Corporation has accepted the tender of John Douglas at £422 for the removal of deposit from the cooling pond at the electricity works.

WATFORD.—The tender of Messrs. Ashworth & Parker, amounting to £42, has been accepted for the pipework for the new economiser.

APPOINTMENTS AND PERSONAL NOTES

Mr. H. S. Dransfield, of Manchester Corporation electricity works, has been appointed junior meters assistant on the electricity staff of the Birmingham Corporation.

Prof. J. H. Dobson has been recommended for the post of electrical engineer to the Johannesburg Corporation. Prof. Dobson at present occupies the position of Professor of Electrical Engineering at the Transvaal University College.

The death is announced of Mr. James Grant, Electrical Engineer to the Bloemfontein Corporation.

A works foreman is required by the Ilford Urban District Council to take charge of the car sheds, shops, overhead equipment, and track. Wages £2 10s. per week. Applications to the Deputy Clerk by January 26th.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

DIRECT UNITED STATES CABLE CO.—The report for the six months ended December 31st states that the half-year's revenue, after deducting out-payments, amounted to £56,335, as compared with £58,268 for the corresponding period of 1907, showing a difference of £1,932 against the half-year under review. The working and other expenses, including income tax, but exclusive of cost of cable maintenance, amounted to £25,357, leaving a balance of £30,978, making, with £2,812 brought forward from the previous half-year, a total available for distribution of £33,790. Interim dividends of 4s. per share for the quarters ended September 30th and December 31st have been declared, and after setting aside £5,000 to the reserve fund account, the balance of £4,506 on the revenue account has been carried forward. The reserve fund account has been debited with £11,043 for the cost of cable maintenance, and £505 for cost of installing acetylene gas light at Ballinskelligs station, and after being credited with interest on the investments, profit on sale of securities, and amount set aside from revenue, there is a balance of £507,890 to be carried forward.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—At an extraordinary general meeting on Friday, resolutions were carried providing for the increase of the company's capital to £500,000. This is to be brought about by the issue of £100,000 6 per cent. cumulative second preference shares with the option to convert into ordinary shares by January 1st, 1914. It is not intended, however, to immediately issue more than £50,000 of the new capital immediately. The new capital is mainly required to meet the normal increase in demand and to pay off a loan. In deference to the wishes of the shareholders, the directors have agreed to issue the shares as £1 shares.

CITY & SOUTH LONDON RAILWAY CO.—The report for the half-year ending December 31st, 1908, states that the receipts from all sources amounted to £86,698, and the cost of working £40,415, leaving a profit of £46,283. Inclusive of the balance brought forward from December 31st last, the net revenue account shows an aggregate total of £48,151. After making provision for the debenture stock interest, rent charge, and the transfer to the renewal fund of £1,500, a balance remains available for dividend of £32,342. Out of this sum the directors recommend that the full dividend of 5 per cent. per annum be paid on the preference stocks, 1891, 1896, 1901, and 1903, and that a dividend at the rate of 1½ per cent. per annum be paid upon the consolidated ordinary stock for the half-year, leaving a balance of £954 to be carried forward. The almost unbroken continuance of fine or mild weather during the latter half of 1908 has told against tube railways in favour of competing cheap transit services operating above ground. This competition, increased rather than relaxed, has been added to by the development of certain new through routes made possible by the opening of new tube railways. Traffic to the value of about £800 was lost by the interruption due to the accident which took place on July 16th, 1908. These adverse influences have been compensated only by such advantages as have been brought to the half-year's working by the lower price of coal, and by the economies that have been effected in various items of expenditure. In the interest of the convenience and safety of passengers, the directors have felt it their duty to undertake certain expenditure (which will entail an ultimate annual charge on revenue of about £400) on permanent improvements at various parts of the system. Most of this expenditure is recommended or approved by the Board of Trade. Among these works will be a new staircase giving access to the surface from the Brighton Company's end of the low level subway connecting the City & South London station at London Bridge with the lifts leading to the platforms of the Brighton Railway Company's station. One-half of the cost of this work will be borne by the Brighton Railway Co. The number of passengers carried during the half-year, exclusive of season-ticket holders, was 10,631,336, compared with 10,732,145 for the corresponding period of last year. The meeting will be held on Tuesday next.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £64 5s. to £64 15s. per ton (last week, £65 10s. to £66 per ton).

METAL SPINNINGS.—Mr. C. H. K. Chamen, a well-known member of the electrical engineering industry in Manchester, has left Messrs. Siemens Bros. Dynamo Works, in order to assist in the development of the business of the Wardle Engineering Co., in which he has acquired the controlling interest. The company manufacture all classes of metal spinnings, an industry which is usually associated with Birmingham; in fact, we believe that the firm is the only one in Manchester in a position to carry out work of this class. A speciality of the firm is their patented "streetlite" ventilated lantern with a non-vibratory suspension, particularly adapted for metal-filament lamps; this was briefly described in one of our supplements on the Manchester Exhibition exhibits last October.

ROBERTSON SOCIAL & ATHLETIC CLUB.—On Saturday last the Social & Athletic Club in connection with Robertson Electric Lamps, Ltd., held their third annual fancy dress dance in the spacious hall at Brook Green Works, Hammersmith. The hall was prettily decorated for the occasion, and the attendance numbered upwards of 350.

TESTS ON METAL FILAMENT LAMPS.—The Westminster Electrical Testing Laboratory have just completed a series of life tests on ten of the principal makes of tungsten filament lamps, the result of which tests will be supplied to subscribers only. The following are the names of the lamps tested:—Aegma, the Electrical Co.; E.M.F., E.M.F. Manufacturing Co.; Sunbeam, Sunbeam Lamp Co.; Adnil, Marples, Leach & Co.; B.T.H., British Thomson-Houston Co.; Sirius, Falk, Stadelmann & Co.; Westinghouse, British Westinghouse Electricity & Manufacturing Co.; Osram, General Electric Co.; Metfil, Edison & Swan Electric Light Co.; Gabriel, Gabriel Electric Lamp Co. Four lamps were tested of each make. All were ordered as for 100 volts, and of 25 to 30 mean horizontal candle-power, with the exception of the B.T.H. lamps, which were rated at 40 c.p. The results of the tests have been printed in full and bound up in one leather-covered volume. The subscription required to obtain one copy of the complete report is £2 2s. Additional copies may be obtained (for personal use only, and not for resale) at £1 1s. each.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the creditors of the Municipal Electric Light & Power Corporation, Ltd., will be held at 37 Essex Street, Strand, London, at 12 noon, on the 25th inst. Notice is also given that the latest date for receiving particulars of claims is February 25th. The liquidator is Mr. E. G. W. Slough.

The first meeting of the creditors in the bankruptcy of George Sutcliffe, trading as Geo. Sutcliffe & Co., electrical engineer, 22 Church Street, Abertillery, Mon., was held on January 13th, at 144 Commercial Street, Newport, Mon., when it was resolved that the matter should remain with the official receiver.

MESSRS. MARPLES, LEACH & CO.—Messrs. Marples, Leach & Co., Ltd., announce that they have appointed Mr. W. M. Davidson their branch manager for Scotland. Their office is situated at Baltic Chambers, 50 Wellington Street, Glasgow, where samples of their various manufactures and special lines may be inspected.

AGENCY.—Messrs. A. P. Lundberg & Sons have appointed Mr. Charles Arnould, 55 Rue de Rome, Paris, their sole agent in France.

The Electrical Trades Benevolent Institution.—It has been decided that a dinner shall be held about the middle of March with a view to furthering the objects of this benevolent institution. A committee is being formed.

London-Berlin Telephone.—Reuter states that there is no foundation for the rumour mentioned in Tuesday's *Evening Standard* that the British postal authorities are engaged in negotiations with the German Imperial Post Office for the establishment of a telephone cable connecting London with Berlin.

Institution Honorary Members.—During the past year the Institution of Electrical Engineers has lost two honorary members, viz., Lord Kelvin and M. E. Mascart. In their place the Council have elected Mr. Oliver Heaviside, F.R.S., and the Hon. C. A. Parsons, C.B., F.R.S. Prof. Schwartz has tendered his resignation as member of the Council of the Institution, which has been accepted.

Summons for Failure to Supply.—An interesting case under the Electric Lighting Clauses Act of 1899 was heard before the Brentford magistrates last week. In June last a house in Copthall Gardens, Twickenham, was purchased by Mr. F. S. Rowton, who, on applying to the Twickenham & Teddington Electric Supply Co. for a supply of current, was informed that he would have to pay a rent of £1 per year for the fittings installed in the house. It appears that the company had wired the building free of charge when it was in the hands of the builder. Mr. Rowton declined to pay this rent, stating that as he had purchased the house, the fittings were now his property. A formal application for supply was made by Mr. Rowton's solicitor, and the company replied that they would supply if the necessary fittings were provided, but they declined to use their own fittings unless these were purchased or hired by Mr. Rowton. For the defence it was stated that if the complainant was correct, all the money spent on the wiring of houses by companies and local authorities would be confiscated if the houses passed by sale to persons who did not make any inquiry as to the ownership of such fittings. It was also asserted that the occupier was not entitled to a supply of current until he had entered into a contract with the supply authorities, and this the complainant had declined to do. After further discussion the magistrates dismissed the summons, on the ground that no proper notice had been served on the company, and as a consequence there was no contract to supply electric current. A sum of £5 5s. was allowed as costs. Mr. Cohen asked leave to appeal, and this was granted.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

IRON POLES, PIPES, &c.—A leaflet from Messrs. John Spencer, Ltd., of Wednesbury, gives prices of an extensive range of iron and steel tubes and fittings, and illustrates various patterns of telegraph, telephone, and tramway poles. The list which we received was accompanied by a round aluminium perpetual calendar, about the size of a five shilling piece.

TECHNICAL TRANSLATIONS.—We have received a calendar from Messrs. Flowerdew & Co., of 14 Bell Yard, Temple Bar, who specialise in technical translation work.

BOILER SETTING.—A handsomely produced book from Messrs. E. J. & J. Pearson, Ltd., of Stourbridge, contains a description of the firm's method of boiler setting with patent asbestos-cushioned seating blocks and angular contact covering slabs. This system avoids a great deal of the heat waste which is incidental to most ordinary brickwork settings. A good deal of useful information relating to boilers is included.

WIRING ACCESSORIES AND LAMPS.—A new catalogue dealing with accessories for lighting and power work is to hand from the Metallic Seamless Tube Co., Ltd., of Wiggin Street, Birmingham. It is useless to give a list of the numerous items included in this list, which covers a wide range, but among the unusual fittings we notice a neat little electrolier suspender and connector, a flush floor-plug, with a spring lid to prevent dust accumulating on the terminals when the plug is not in service, an automatic self-closing wall socket in which the withdrawal of the plug automatically closes all working parts, rendering the socket watertight, and several new patterns of lamp-holders, including the "Automat," in which no screws are used for connecting. The "Metallic" metal-filament lamps are also listed. Important features of this catalogue are the systematic method of allotting each article a number and code word, and the statement of the scale alongside each illustration.

FLAME ARC LAMPS.—A leaflet from the Abbey Electric Co., of 17 Victoria Street, Westminster, describes the "Abbey" flame arc lamp. The chief features of this lamp, which is of the converging carbon pattern, are the very simple mechanism and the absence of any special magnetic control of the arc. The lamp is of British manufacture throughout. It can be obtained in two sizes, for 12 or 20 hours' burning, with one pair of carbons. Lamps for both direct and alternating current are supplied, and the firm also stock "white" and "yellow" flame carbons. A sketch of the mechanism of this lamp was given in ELECTRICAL ENGINEERING, Vol. IV., Manchester Exhibition Supplement, page 46.

SMALL MOTORS FOR DRILLS, &c.—We have received a leaflet from Marples, Leach & Co., Ltd., of Adnil Building, Artillery Lane, London, E.C., on which are illustrated several small motor combinations, including a ¼-h.p. polishing and buffing machine, a sewing-machine (series motor) equipment, a three-speed drill, and other examples of this class of work. Besides these combinations, the standard patterns of A.C. and D.C. motors of from $\frac{1}{16}$ to ⅛ h.p., manufactured by this firm, are also listed. The smallest sizes can be obtained series wound only, but it is stated that shunt-wound motors of only $\frac{1}{20}$ h.p. will shortly be put on the market.

FUSE WIRE.—A leaflet from the Edison & Swan United Electric Light Co. describes a special brand of Ediswan fuse wire made of an alloy named pyrotin, which, although cheaper than ordinary fuse wires, is less liable to mechanical injury and does not depreciate by oxidising or scaling. The wire is wound on metal ½ lb. and 1 lb. reels, each enclosed in a tin-box.

SMALL ACCUMULATORS, CARRIAGE LAMPS, AND ACCESSORIES.—A new catalogue is being issued by Messrs. Peto & Radford, of 100 Hatton Garden, dealing with a great variety of patterns of small accumulators for ignition carriage lighting and similar purposes, including the "armoured type," specially intended for motor-car work, in which a considerable degree of support is given to the plates. Another pattern is the Ashstead accumulator, with a particularly porous positive plate. Larger batteries for lighting and traction are also included. Other items in the catalogue comprise charging boards, fittings for carriage lighting, and garage lighting, hand lamps, switches, instruments, and various accessories.

College Training of Engineers.—Whether the business side of engineering should be introduced into college curricula or not is still a debatable question among educational authorities. According to the *Times*, a lectureship in "Specifications and Accounts" has been established in connection with the Faculty of Applied Science in the McGill University, Montreal. Mr. R. A. Ross, a member of a firm of consulting engineers, has been appointed the first lecturer.

A NEW ELECTRIC GRINDER

THE accompanying illustration shows a new electric grinder recently constructed by Messrs. Kramos, Ltd., of Bath. It is a very powerful tool, and consists of a motor giving an output of 1 h.p. at 3,000 r.p.m., which carries a wheel 8 in. by 1 in. The motor is shunt wound, and the end bearing is prolonged 8 in., so that the machine can be used for internal work or grinding at angles when required. The machine shown

"KRAMOS" ELECTRIC GRINDER.

is provided with tool post to fit lathe slide rest, but when desired to fit on a lathe saddle this can be omitted and a suitable base provided. Double ball thrust washers are fitted, and the whole machine is completely enclosed. Fifteen feet of flexible cable is provided, and the machine can be operated from any lamp-holder. As is well known, Messrs. Kramos construct many other types of electric grinders of the self-contained and flexible shaft types, and also portable electric drills.

The Electrical League.—A meeting is to be arranged between the provisional committee of the Electrical League, representatives of the technical press, and other gentlemen interested in similar objects to those of the promoters of the Electrical League, at which Sir William Preece has consented to preside. The day for this meeting will be fixed in due course. In the meantime, Mr. H. Borlase Matthews, Hon. Secretary of the Electrical League (1 Victoria Street, Westminster, London, S.W.), will be very pleased to hear from secretaries of any companies who will undertake to distribute a certain number of the pamphlets referred to in our last issue, indicating the scope of the League. Mr. Matthews also informs us that he will be glad to forward a copy of the pamphlet to anyone who is interested in the matter, and who has not already received one of the pamphlets in question.

Power Station Fatality.—On Sunday, January 10th, a labourer of Gateshead, named C. W. Paul, was so severely burned by coming into contact with the live portion of a 20,000-volt switch that he died the same day. Deceased was in the employ of the Durham County Electric Power Supply Co., and was engaged in cleaning out a high-tension switch chamber. The chamber contained six panels, in separate compartments, one only of which was alive. The man had been told not to touch this panel, and was working with another man at the time of the accident. At the inquest on Friday last, the jury decided that the burns which caused the man's death were accidentally received.

Proposed Engineering Exhibition at Manchester.—A number of representative Manchester engineering firms were present on Thursday, January 14th, at the Midland Hotel, to discuss the desirability of holding a General Engineering Exhibition in that city in the year 1910. The meeting was called by the International Trade Exhibitions, Ltd., of Broad Street House, London, who were the organising managers of the recent Electrical Exhibition held in Manchester, and the suggestion made by this company was that the exhibition, should it take place, should be promoted by a committee appointed by the industry, representing the various sections of the engineering trades, and representatives of engineering institutions, who should be the virtual proprietors of the undertaking, and who should have full conduct of the exhibition, employing the company as organising managers and business contractors. The meeting was entirely favourable to such an exhibition being held, and a provisional committee of nine engineering firms representing different sections was appointed. A further meeting was arranged at the Midland Hotel, Manchester, for February 17th next, with a view to inviting representatives from the whole of the engineering trade to be present.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

In a lecture on Power Supply in the United Kingdom, before the Royal Society of Arts on Monday last, Mr. G. L. Addenbrooke dealt with the working expenses of large power supply undertakings. After arriving at some figures for the average prices which would have to be obtained to make the supply profitable, the lecturer compared them with those obtained in the case of private generating plants. The results of the comparisons were favourable to public supply. (Page 82.)

The Home Office electrical regulations, which were given in full in our last issue, will come into force on July 1st next, except as regards stations constructed before July of last year, in respect of which they will come into force on January 1st, 1910. (Page 83.)

A record in long-distance telegraphy was established last week, when the Indo-European Telegraph Co. succeeded in communicating direct with Calcutta, from their London office, a distance of 6,900 miles. This long transmission was accomplished on the Wheatstone automatic system with the aid of thirteen relay stations. (Page 83.)

The Paper by Dr. M. Kloss on the rating of turbo-alternators, which was read at Manchester in November last, was again read and discussed at Birmingham recently. In the latter discussion, the use of the Tirrill regulator, when close regulation was required, was advocated by one speaker, and another preferred to employ choking coils of the saturated core pattern. The questions of forced ventilation and the heavy shocks experienced by alternators on short-circuit were also brought up. (Page 84.)

On the occasion of the laying of the foundation stone of a new hospital last week, the marquee erected for the purpose was both lighted and heated electrically. The designs of the architect for the hospital include some unusual features with regard to the electrical equipment. (Page 84.)

In a Paper by Mr. D. S. Munro, at Glasgow, the various systems of wiring, with their advantages and disadvantages, are described and compared. Several practical suggestions and hints with regard to house-wiring are contained in the Paper, and the want of a good and cheap method is emphasised. The author suggests that the solution to the problem will be a form

Digitized by Google

of cable manufactured in long lengths, with its metallic connection complete, and delivered in coils. It should be soft enough to unwind, bend, and straighten easily, and should be enamelled after bending and straightening to prevent electrolytic troubles. He suggests a thin seamless copper covering fitting tight over the insulated wires. (Page 85.)

WE publish this week an illustrated article on the development of the Lancashire Electric Power Co.'s system. The most noticeable features are the extended use of overhead lines, and the extreme simplicity of the sub-station arrangements. Considerable economies have been arrived at at some of the works where electric power has replaced individual steam drive. (Page 87.)

A LETTER asking for information as to the results of competition between electric power and suction gas has been sent to the engineers of supply undertakings throughout the country by Mr. F. L. V. Mathias, Borough Electrical and Tramways Engineer, Warrington, to which a number of replies have been received. (Page 91.)

UNDER Electrometallurgy and Electrochemistry is a note on the preparation and properties of silundum, a product of the electric furnace, intermediate between carbon and carborundum. A review of the French electrometallurgical industry is also given, and a new method of removing grease from metals to be electroplated is described. (Page 92.)

IT has been officially announced in Johannesburg that the scheme prepared by Messrs. Harper Bros., of London, for the supply of electric power to fifteen mines on the Rand has been accepted, and that the Victoria Falls Power Co. will co-operate in putting the scheme into effect. (Page 93.)

AMONG the specifications published by the Patent Office on Thursday last were two by the Rapid Magnetting Machine Co., Ltd., H. H. Thompson, and A. E. Davies for improvements in magnetic separating machines. The first related to machines of the rotary pattern, and the second to those of the reciprocating pattern. In both cases the improvement consisted in substituting a working surface of alternate strips of magnetic and non-magnetic material for the usual non-magnetic surface. A specification by the British Insulated and Helsby Cables, Ltd., and D. B. Saunderson, describes a method and apparatus for welding wires and cables with the aid of fusing compounds. A method of mounting the wheel of a trolley pole so as to allow a certain amount of lateral movement with respect to the pole is patented by J. Shepherd and F. B. Ullery, and a flexible shaft coupling for turbo-generators is described in a specification by Siemens Bros. Dynamo Works and Dr. M. Kloss. A patent by S. Eisenstein relates to multiple working in wireless telegraphy, and a steel collector of brush form for a surface-contact system, is described in a specification by the S. P. Syndicate, Ltd., and H. M. Sayers. A patent granted to the Felten Guilleaume Akt.-Ges. for a method of enclosing wires with a loose insulating cover expires during the current week. (Page 94.)

A LETTER from "Fairminded" continues the criticism of our "Pessimistic Correspondent's" article on power companies.—Mr. A. W. Bennis writes regarding a prospectus of a company for manufacturing smokeless furnaces. (Page 95.)

THE Ilford ratepayers have passed a resolution urging the Council to appoint a tramways manager, on the ground that the dual position of electrical engineer and tramways manager involves too much work for one official.—The new London County Council tramway over Putney Bridge have the tracks laid on either side close to the kerb.—Through bookings are being arranged between the London County Council tramways and the West Ham tramways.—Both the Manchester and Liverpool Corporations have accepted the recent adverse votes of the ratepayers in regard to the adoption of the trackless trolley system, and will not insist upon a poll.—The Oldham Corporation have decided not to omit or modify, as requested by the local electrical contractors, the clause in their Bill dealing with electric fittings.—Sir Alex. Kennedy is to advise the Oxford Corporation on the tramway question.—The Southport Corporation, at the suggestion of the local electrical contractors, have decided in future not to sell fittings at their showroom.—Further details of the scheme for the construction of the tunnel under the Tyne between North and South Shields, have been placed before the respective Corporations. (Page 97.)

A BATTERY and booster is required by the Manchester Waterworks Committee, and a Lancashire boiler at Llandudno Electricity Works.—A report upon electric supply at the Belfast Harbour Works has been presented, involving an expenditure of £12,000.—Stores are required by the Marylebone and Bermondsey Councils. (Page 99.)

AT the meeting of the City and South London Railway Co., on Tuesday, it was stated that the precautions being taken to prevent another outbreak of fire in the tunnels were greater than those required by the Board of Trade.—The conversion of the East London Railway to electric traction is indefinitely postponed.—New issues of capital are being made by the Chiswick Electricity Supply Corporation and the Anglo-Argentine Tramways Co. (Page 100.)

A THOROUGHLY practical Paper on house wiring was read by Mr. D. S. Munro at the last meeting of the Glasgow Local Section of the Institution of Electrical Engineers. He dealt in an outspoken manner with many of the questions with which the house-wiring expert has to deal, and he certainly suggests that some of the more expensive precautions identified with "first-class" work are not really necessary in the majority of installations. For concealed work in the walls of buildings erected with a view to permanence, however, we are of opinion that nothing lighter than the heaviest gauge of solid-drawn screwed barrel should be employed—in fact, some contractors in London go further than this, and prefer to use galvanised iron barrel under cement floors and plaster, or else a much heavier tube than the standard house conduit. Certainly in such situations a brazed tube is undesirable, as it gives false security. It is in surface work, and ordinary work under wooden floors, that considerable economy can be practised. Each case must, of course, be considered on its merits: in some places a steel conduit system may be desirable, either the simple split tube or welded tube, according to the degree of security necessary; in others, wooden casing may be preferable, or, again, a plain system of wires on cleats, or insulated rings may be sufficient. With regard to the last-mentioned system, it was recently pointed out to us by a contractor in the North of England, who has a good knowledge of Continental practice, that there is a false idea in this country that "flex" is customarily employed for this purpose. It is true that the insulation of the wires run on the insulating rings resembles that which is employed on our "flex," but, as a rule, the conductors are either single wires or ordinary 7- or 19-strand. Further, there is no reason why the conductors employed for suspending pendants in the ordinary way should be made up of a large number of strands of 36 or 40 gauge wire; a 7-strand or 19-strand conductor with larger wires would be far more suitable.

Digitized by Google

for the purpose, much easier to handle, and, last but not least, cheaper. This was pointed out incidentally in an article in ELECTRICAL ENGINEERING two years ago (Vol. I., p. 80); but the Cable Makers' Association has its standards—which, it is whispered, have even been followed by some of its members in making their "non-association" grades of wire—and a "special" wire would entail a special price to the purchaser, whether its cost of manufacture were greater or less than that to the standard specification. If one or two of the large wiring contractors were to standardise their own system of surface wiring on insulators with a 7- or 19-strand wire suitable alike for the fixed wires and pendants, they would find that, with a little insistence, they could supply the cheap house wiring that is certainly required in the present condition of the electric lighting business.

THE employment of wireless telegraphy for communication to and from ships at sea, has now become so common that the enormous benefits this application of electricity has conferred on mankind has been apt to be forgotten. The part it played in connection with the rescue of the passengers of the White Star liner *Republic*, after her collision with the steamship *Florida*, on Saturday, in a dense fog in the Atlantic, however, must be written down prominently among the greatest triumphs of applied science. Had it not been for wireless telegraphy, the list of lives lost on this occasion would have been a long one, for by no other means could the ships in the neighbourhood have been communicated with in the fog; moreover, the way in which the *Baltic*, the *Lucania*, the *Lorraine*, the *Furnessia*, and other ships were able instantly to respond and to seek the disabled vessel in the fog, shows that the procedure in the case of signals of distress has been efficiently organised. Again, apart from the mere reception and acknowledgment of the distress signals, the increased feeling of confidence, not only to those in charge of the vessel, but also to the passengers, which is engendered by the receipt of what amounts to a verbal reply that help is forthcoming, has also a most valuable moral effect. That every detail has been carefully thought out in the equipment of the wireless telegraph installation is shown by the fact that the operator on board the *Republic*, after sending out broadcast the Marconi Co.'s conventional distress signal, "c.q.d." (which, it appears has not yet been superseded by the - - - — — — - - - of the Berlin Convention), was able to keep up a continual exchange of instructions and information to the invisible ships around with the battery provided for such emergencies, after the engine-room had become flooded, and it was no longer possible to work at full power. From the reports which have been received, it appears also that the wireless telegraph room was also flooded, and that the operator Binns stuck to his post continuously throughout the day from the time of the collision to the rescue, with the exception of brief intervals for food, which, it is said in one account, necessitated his literally swimming to the pantry to procure it. With characteristic promptitude, a member of the House of Representatives has already introduced a Bill to make it compulsory for all ocean-going steamers carrying passengers to have wireless telegraph installations, and a clause might with advantage be added to make it compulsory in such cases to carry a relief operator.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JANUARY 28TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, London. Paper to be read :—"The Parallel Operation of Alternators," by Dr. E. Rosenberg.

FRIDAY, JANUARY 29TH.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, St. John Street, Clerkenwell. Paper to be read :—"Brakes and Brake Gear," by J. C. Rennie.

North-East Coast Institution of Engineers and Shipbuilders.

7.30 p.m. Meeting at the Literary and Philosophical Society, Westgate Road.

SATURDAY, JANUARY 30TH.

Electrical Football League.

2.45 p.m. The following matches will be played :—Robertson Lamps *v.* Ediswan, at Gunnersbury Avenue; St. James Electric *v.* St. Pancras Electric, at Wormholt Farm.

MONDAY, FEBRUARY 1ST.

Royal Society of Arts.

8 p.m. Cantor Lecture III., on "Electric Power Supply in the United Kingdom," by G. L. Addenbrooke.

TUESDAY, FEBRUARY 2ND.

Electro Harmonic Society.

8 p.m. Concert (Ladies' Night) in the King's Hall, Holborn Restaurant.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology. Paper to be read :—"Automatic Devices for Tramway Working," by J. G. and R. G. Cunliffe.

WEDNESDAY, FEBRUARY 3RD.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. Meeting at 92 Victoria Street, London, S.W. Paper to be read :—"The Direct Current Variable Speed Motor and its Application to Modern Machine Tools," by W. S. Lonsdale.

THURSDAY, FEBRUARY 4TH.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Dr. Howard Pirie will open a discussion on "The Transport of Ions."

Wiring Rules.—The Phœnix Assurance Co., Ltd., of 70 Lombard Street, London, E.C., will be pleased to forward a copy of the latest edition of their wiring rules, free of charge, to any of our readers who apply for them. The rules in question are so complete that they almost constitute a treatise explaining the difference between good and bad work in electrical wiring, and they will doubtless prove useful even to those firms whose customers do not insure with the Phœnix Fire Office.

Wireless Telegraphy.—The Admiralty have decided to erect a wireless station on the top of Gastland Hill, overlooking Rosyth, in connection with the new naval base. A mast, 160 ft. in height, which will consist of three lengths of Oregon pine, is to be erected. This will enable the new naval base to be in direct communication with the Admiralty in London, as well as with warships at sea.

It is reported that Mr. Marconi has carried out successful experiments in duplex working in wireless telegraphy, and has filed patents relating to apparatus for this purpose; with the aid of this auxiliary apparatus it will be possible to send and receive messages simultaneously at the same station and thus considerably increase its working capacity.

In accordance with the arrangements made by the Meteorological Office, wireless weather reports will be sent after the 1st of next month from ships in the following lines :—Allan, American, Anchor, Atlantic Transport, Canadian Pacific, Cunard, Dominion, Red Star, and White Star. The co-operation of the Deutsche Seewarte, the German Meteorological Office at Hamburg, has also been secured.

An experimental wireless telegraph station has been fitted up at Armstrong College, Newcastle, the antennae being stretched between the two towers of the main buildings. Messages have already been received from Cullercoats. The station has been fitted up under the superintendence of Professor Stroud and Mr. Morris-Airey, who intend to carry out a series of experiments on the Poulsen arc system.

The 450-ft. tower of the Machrihanish Station, which was intended for transatlantic communication on the Fessenden system, and which collapsed in December, 1906, during a gale, is to be reconstructed. The buildings and machinery have been kept in good condition in the interval which has elapsed. It is stated that the delay in reconstruction was due to the fact that the results of certain experiments were being awaited.

We understand that a contract has been obtained by the Marconi Wireless Telegraph Co. for ten new ship wireless stations for the Italian Government. This is in addition to the 30 land and ship stations already equipped by the company for the Italian Government.

ELECTRIC POWER SUPPLY IN THE UNITED KINGDOM

THE second of the three Cantor lectures by Mr. G. L. Addenbrooke on the above subject, which was delivered on Monday evening before the Royal Society of Arts, commenced with a consideration of the working costs of stations of such size as were given in Table I. (see ELECTRICAL ENGINEERING, January 21st, page 56). As a basis for this investigation, the lecturer put forward the figures given in Table II. The number of units sold per annum, given in the third column, followed, he said, from the figures for output and load factor, and the lbs. of coal used per unit sold had been deduced from the

Table II.—*Station Working Data.*

Output of station. kw.	Load factor. per cent.	Units sold per annum.	Lbs. coal per unit sold.	Coal cost per unit sold. d.
2,500	26	5,700,000	5·25	0·188
5,000	28	12,200,000	4·50	0·160
10,000	30	27,000,000	4·00	0·143
20,000	32	54,000,000	3·50	0·126
40,000	34	116,000,000	3·25	0·116

Table III.—*Annual Working Expenses.*

Output of station. kw.	Admin. and labour £	Coal, oil, water and stores. £	Rent, rates, taxes, and insurance. £	Repairs and maintenance. £	Total working costs. £	Cost per unit. d.
2,500	4,200	4,900	1,500	2,500	13,100	0·55
5,000	6,500	8,900	3,000	4,000	22,400	0·44
10,000	11,000	16,000	6,000	7,500	40,000	0·36
20,000	18,000	30,000	12,000	12,000	72,000	0·32
40,000	30,000	60,000	24,000	22,000	136,000	0·28

Table IV.—*Revenue and Selling Price.*

Output of station. kw.	Total working costs. £	Interest and Deprec. £	Total revenue. £	Selling price per unit. d.	Private supply. d.
2,500	13,100	12,600	25,700	1·10	0·68
5,000	22,400	20,700	43,100	0·85	0·51
10,000	40,000	35,100	75,100	0·67	0·40
20,000	72,000	59,400	131,400	0·58	0·35
40,000	136,000	104,400	240,400	0·50	0·30

best modern practice. Assuming the calorific value of the coal used as 11,500 to 12,000 B.Th.U. per lb., the largest station would use on an average some 38,000 B.Th.U. to supply one kw.-hour. Thus it resulted that the overall efficiency of the plant was of the order of 8½ per cent. For the 2,500-kw. station, this figure was about 6 per cent. This was up to the consumers' motor terminals, and if the losses in the motors were included, the above efficiencies would be reduced to about 7¼ and 5¼ per cent. respectively. The price of the coal has been taken as 6s. 8d. per ton. The working costs given in Table III. included distribution to large consumers and transformation from high to low pressure. The costs of administration and labour could be taken as about equal. The amount allowed for repairs and maintenance was taken as about 2½ per cent. on the value of the plant. This did not include depreciation, which was taken as 3 per cent. of the capital expended. As cable-makers had agreed to maintain distributing systems for an annual charge of 1 per cent. of their cost, this left a substantial sum for the rest of the plant. From the above figures of working expenses, the total costs per unit, excluding interest on capital and depreciation, could be obtained, and these were given in the last column of Table III. It would be observed that the costs decreased from rather over one half-penny per unit sold to a little over a farthing, as the scale of operation was increased.

In Table IV., the total working costs were repeated in the second column, and in the third column figures for interest and depreciation were given. These were taken at 6 per cent. and 3 per cent. respectively on the total capital. In work by local authorities, the allowance for interest and sinking fund under this head was often not more than 6 to 6½ per cent., but, in the lecturer's opinion, power supply was a trading adventure which ought to carry on an all-round profit of at least 5 per cent., and if corporations embarked on the work with the intention of working on a less margin of profit, they were mortgaging their other assets for at least the difference. It would be noticed that this 9 per cent. amounted to nearly as much as the total working costs, and it was a feature of this class of work that there was a tendency for a fair interest and depreciation on the capital involved, to amount to as much as the other total annual costs and charges. The total of these two figures gave the gross revenue to be earned, and finally, in the last column, the average prices which would have to be obtained per unit were given. It would be noticed that there was a difference of over 50 per cent. in favour of the largest undertaking and nearly that for the 20,000-kw. undertaking. This latter was the size of station which it was likely to pay best to erect within the next 10 or 15 years. Two or more such stations could be erected within six or eight miles of each other and run in parallel, feeding the same network of distributing mains. This was now done on a large scale in the Newcastle district and in a number of places on the Continent. The selling prices given in Table IV. were, of course, average prices. From the smallest station, energy for lighting would be sold in bulk at, say, 1½d. per unit, and the smaller classes of power users would be charged at about the same price. Most of the power work would be spread over a time represented by a power factor of about 35 per cent., and it would be possible to charge such power consumers lower prices than the average shown, as, for example, 0·85 to 0·9d. per unit. In general, however, a station of 2,500 kw. capacity was too small for giving a supply of power in a district where the average private plants were of any considerable size. The effect of the load factor on the average price obtained was very evident. The capital charges were not increased, but were spread over, say, three times the number of units sold; the same applied to administration, rates and taxes, and labour. The coal was increased, but as there were no more stand-by losses about twice the quantity of coal would suffice to generate three times the number of units. Consequently for nearly continuous loads, such as pumping, half the prices shown in the table would be remunerative, and thus it would be seen how in very favourable circumstances, as in the case of current supplied in very large quantities for electrolytic purposes to a customer near the station, a price as low as 0·2d. could be reached.

The above figures should now be compared with those obtained in the case of a private supply. Taking the smallest size of station in the table, the capital cost would be little more than that for the plant alone; administration and labour would be reduced to about one-half; coal would be, say, 10 per cent. less; rates and taxes not more than half, and repairs about three-quarters that given in the table. Leaving the rates of interest and depreciation the same, which was in favour of the private supply, it would be found that for an average load factor of 26 per cent. the cost would come out at about 0·68d. per unit, instead of 1·10d., and this agreed with published results of modern plants. Comparing this with the costs for large public stations, it would be seen that a 10,000-kw. station can well compete on a pure cost basis with a 2,500-kw. private supply plant. In general, however, the h.p. installed in motors in individual industrial works would be far below 1,000 h.p., and thus smaller stations would be able to compete. In general, it was advisable that the capacity of the supply station should be about ten times that of its largest customer.

The lecturer then turned to the engineering side of the question, and considered in detail the arrangement and construction of the various parts of a modern power station. He thought that too much had been made of the value of water facilities, but emphasised the importance of economy in the boiler house. It would, he thought, be most economical to separate the furnace from the boiler, burning the coal in a producer, and then to utilise the hot gases in the boiler. In this way better regulation of the air supply and many other advantages could be obtained The coal-handling and condensing plant, the generating machinery, and the switching arrangements were all dealt with by the lecturer, but owing to lack of space we are unable to include his remarks on these subjects.

The New Patent Act.—A *Reuter* Washington cable states that after a heated discussion, the National Board of Trade, at its final sitting, appointed a special committee to urge Mr. Root, Secretary of State, to incorporate in any treaty the Government might be about to conclude with Great Britain some provision for the protection of American patent rights.

Royal Meteorological Society.—The annual meeting of this society was held on Wednesday, January 20th, at the Institution of Civil Engineers, when the President, Dr. H. H. Mill, delivered an address on the aims of the society. After a vote of thanks to Dr. Mill for his services during the past year had been passed, Mr. H. Mellish was elected president, and Mr. F. Campbell Payard and Commander F. W. Caborne secretaries for the ensuing year.

THE HOME OFFICE ELECTRICAL REGULATIONS

THE regulations proposed by the Home Office for application to premises coming within the Factories and Workshops Act, 1901, which formed the subject of a lengthy inquiry by Mr. James Swinburne, have now been issued as an official document. The regulations, which were given in full in our last issue, will come into force on July 1st, 1909, except as regards such parts of electrical stations as were constructed before July 1st, 1908. For these, the new regulations will come into force on January 1st, 1910.

DIRECT TELEGRAPHY FROM LONDON TO CALCUTTA

A RECORD in long-distance telegraphy was accomplished on Saturday, when, on the occasion of a demonstration at the offices of the Indo-European Telegraph Company, of through working between London and Karachi, direct signals were exchanged with Madras, Calcutta, and Bombay. A new land line 1,574 miles in length has been constructed between Teheran and Karachi by the Indo-European Department of the India Office, and in the early part of last year, automatic relay stations were established on this line at Teheran, at Kerman, and at Panjgur, in Indian Beluchistan. After months of experimental work, direct public communication between London and Karachi was established on Wednesday of last week.

The advantage of through working, apart from the increased accuracy due to the elimination of retransmission, is the high speed of working which can be attained. With the Wheatstone perforated slip transmitter a speed of over 40 words per minute can be reached and a long message of about 350 words was accurately received from Karachi on Saturday in less than eight minutes. At Karachi, connection is made with the telegraph system of the Indian Government, on which the Wheatstone automatic working is used, and after the above and other messages had been exchanged with Karachi, connection was made by means of automatic relay stations at Karachi and Agra, through to Calcutta, Bombay, and Madras, the last-mentioned being reached directly for the first time. As the distance covered in communicating direct with Calcutta is over 6,900 miles, this constitutes a record in long distance telegraphy.

Between London and Teheran there are ten automatic relay stations, and direct Wheatstone automatic working between these cities, a distance of 3,800 miles, has been used exclusively since 1903. In the year 1905 direct working was extended from London, to Manchester and Liverpool. As above mentioned, there are two relay stations on the new line from Teheran to Karachi, so that including the station at Teheran, direct working is accomplished between London and Karachi, a distance of 5,374 miles by means of thirteen automatic relay stations. It should be mentioned that a Wheatstone receiving instrument can be put in circuit at each relay station, and by this means it is possible to find out which section of the line or which relay apparatus is faulty if the messages are not being received distinctly. With the exceptions of two short lengths of cable between Lowestoft and Emden and across the Straits of Kertch, respectively, the line runs across country, much of which is wild and rugged, and in Persia the difficulties of maintaining the line in good condition are so severe that control stations have been erected every 20 to 25 miles.

Up to some eight months ago, the paper slips for passing through the transmitting apparatus were perforated by hand, but this operation is now done with the aid of a device known as the Kotyra keyboard perforator, which has been especially developed for use with the Wheatstone system. This apparatus consists of three electromagnets and a keyboard. The former are mounted side by side on a framework of metal designed to accommodate an ordinary Wheatstone perforator immediately underneath. Three brass pads, one fixed to each plunger, abut on the dot, space, and dash keys respectively of the perforator, and when an electromagnet is energised, a smart blow is given to the respective key of the perforator, and a dot, dash, or space signal is punched. A pinion driven by an electric motor runs beneath the whole of the keys. Each key has a lever connected to it, on the under side of which is a rack. When a key is depressed, the rack engages in the pinion, and is carried along a certain distance, after which it is returned to its position of rest, by means of a spring. The key is then permitted to rise back to its normal position. A contact spring is fitted to each lever, and this spring passes over a series of metallic studs when the rack is in contact with the pinion. These studs are connected to the electro magnets, and as the contacts are rubbed by the spring, the corresponding electromagnets are successively energised, and the paper punched. The coils of the electromagnets, and also the motor, are wound for any voltage between 80 and 120, and the current taken by the apparatus is about 0·6 ampere intermittently. The strength of the magnets is such that a four-slip Wheatstone perforator can be operated, thus making it possible to produce four slips simultaneously, which can afterwards be transferred to four different transmitters. A number of these machines arranged for punching eight slips on pneumatic sets have been supplied to the General Post Office, and in one special case no fewer than twelve slips are obtainable.

Semi-underground Railway in Berlin.—According to the *Elektrotechnischer Anzeiger*, an innovation in railway construction will be made in the development of the railways in Greater Berlin, in that the section Schöneberg-Wilmersdorf will be constructed below the surface of the streets on the same level as the early "covered in" underground railways, but will not be roofed over. This construction will be much cheaper than the underground construction, and safer and less unsightly than a surface railway.

Liverpool Engineering Society.—A lecture on wireless telegraphy and telephony was delivered before this society by Professor E. W. Marchant, on Wednesday, January 20th. Speaking on the subject of tuning, the lecturer pointed out that if a receiver had been so adjusted as to respond only after receiving fifty complete waves of equal length and intensity, a single wave fifty times as strong would cause the receiving apparatus to respond at once so that it was always possible to pick up signals from high-power stations within a certain radius, even with an untuned receiver. Methods had been devised, however, whereby overhearing with tuned circuits was rendered practically impossible by using a prearranged series of different wave-lengths for the signals. The better effects obtained with long wave-lengths were to be explained by the greater absorption of the shorter waves by the atmosphere. In daylight, the air was a better conductor owing to ozonisation by the sun, and consequently messages were received easier by night. The discharging effect of light on the aerial might also be one of the causes for this.

British Association: Winnipeg Meeting.—Some particulars are now to hand of the next meeting of the British Association, which will be held in Winnipeg during the last week of next August. The Publications Committee of the Winnipeg Local Executive Committee of the British Association have issued an illustrated guide to Winnipeg and the surrounding district for the convenience of visitors. This contains, besides a large number of photographic views, much statistical information relating to the growth of Western Canada, and maps of the Dominion of Canada and of the city of Winnipeg respectively. The president-elect is Prof. Sir J. J. Thomson, and according to the *Times* the following are some of the sectional presidents:—Mathematical and Physical Science, Prof. E. Rutherford; Chemistry, Prof. H. E. Armstrong; and Engineering, Sir William H. White. The above-mentioned handbook, which includes the proposed programme of visits, and an estimate of the travelling expenses, may be obtained from the office of the British Association, Burlington House, W., or will be sent to applicants enclosing 2½d. for postage.

THE RATING OF TURBO-ALTERNATORS

AT a meeting of the Birmingham Local Section of the Institution of Electrical Engineers held on the 15th inst., the Paper by Dr. M. Kloss on "Practical Considerations in the Selection of Turbo-Alternators," which was read at Manchester on November 3rd, was again read and discussed. An abstract of the Paper and the ensuing discussion at Manchester was given on page 657 of ELECTRICAL ENGINEERING for November 12th, and the written reply of Dr. Kloss to that discussion will be found on page 694 of the issue of November 26th. It will be remembered that Dr. Kloss emphasised some of the leading differences between slow-speed and high-speed alternators in regard to the necessity for artificial ventilation, the fact that such close inherent voltage regulation was not attainable with turbo-alternators as with slow-speed machines, and the influence of the amount of margin allowed in the specification of the rated load factor on the price of the machine.

Mr. A. R. EVEREST (British Thomson Houston Co.), who opened the discussion at Birmingham, said that he agreed with practically all the author's statements. He considered that for machines up to 5,000 kw., natural ventilation was quite satisfactory. With regard to regulation, a saturation factor of 0·6 was rather too high to take, although the flatter the curve the better the regulation. The author did not mention the heavy shocks experienced on short circuit; he had found from oscillograms that on short circuit the current increased momentarily up to 16 to 17 times full load current, and after 5 cycles was still 8 or 9 times the full load current. Of course, close regulation made matters worse on short circuits. He advocated the use of a Tirrill automatic regulator operating on the exciter when close regulation was required. He had only found it to be unsuitable when the supply for the exciter system was used for other than excitation purposes, as the voltage was then unsteady. He quite agreed with the author's statement as to the pronounced effect which the power factor had on the regulation.

Mr. A. M. TAYLOR (Birmingham Corporation Electricity Department) wished to know why the voltage drop on load was not given by designers of alternators instead of the rise in voltage on throwing off the load.

Dr. D. K. MORRIS, referring to the question of regulation, suggested that instead of the Tirrill regulator, choking coils of the saturated core type, as described in the Paper read by Mr. Morcom and himself, should be used. He regretted that he had not any figures obtained in practice to prove his point in favour of the use of these choking coils, but he was now carrying out experiments in this connection, and felt quite certain that by their use good and efficient regulation would be obtained.

Dr. J. D. COALES (Birmingham University) wished to know whether a rotating armature could not be used instead of a rotating field, and thereby closer regulation obtained.

Dr. KLOSS, in reply, gave two reasons why the drop on load was not stated by designers instead of the rise in throwing off the load; the first being that the drop was bound to be larger than the rise, and therefore designers did not like to draw attention to it, and the second and more practical reason was that if there was a large rise it was apt to do damage if the load was suddenly thrown off, and therefore this rise should be known by the purchaser. The objection to Dr. Morris's proposal to use choking coils for regulating purposes appeared to be that they would absorb energy continuously, and their use would therefore be unsound commercially. In reply to Dr. Coales, the employment of a rotating armature would certainly help the regulation, but such armatures could not be used owing to the difficulty in collecting the current at high voltages.

ELECTRICAL EQUIPMENT OF A HOSPITAL

A Temporary Heating Installation

THE laying of the foundation stone of the new Hospital for Invalid Gentlewomen, Lisson Grove, by H.R.H. the Duchess of Albany, on the 18th inst., was the occasion of a somewhat novel departure in electric heating. By arrangement with the Electricity Department of the St. Marylebone Borough Council, the marquee erected to accommodate the audience, besides being lighted electrically, was heated throughout by means of several electric radiators and convectors, it being recognised that electricity was the only safe and hygienic agent in such circumstances. The designs of the architect for the hospital, Mr. Claude W. Ferrier, include a comprehensive system of lighting and heating, and electric lifts, surgical appliances, telephones, and clocks are to be installed. A noteworthy point in the first item is that such lights as have to be accessible from the patients' beds are to be controlled by switches fitted with cords, so as to avoid any risk from live flexible wires. An electric passenger lift will be installed of sufficient size to carry the patients on their beds from the ambulance entrance level with the street direct to every floor of the building, and into the anæsthetising room of the operation department. The control will be by push buttons, with automatic locking to all the doors, and both shaft and doors will be fireproof. The operating theatre is of particular interest, as it will be ventilated and heated by means of electric inlet and outlet fans. The air from the former will be warmed electrically, this being the most suitable means of maintaining an equable temperature, which is a very essential point. Without a heated inlet the temperature of the room would be liable to a very quick fall, owing to the rapid change of air. This special arrangement is also necessitated by the fact that the theatre will probably require heating when it is not necessary to run the general heating system of the building. The speed of the fans and the regulation of the heaters will be controlled by resistances fitted at the back of a marble panel, and so placed that, while being accessible from the outside of the theatre only, the regulating handles will be on the inside. This is done with a view to minimising surfaces difficult to sterilise. Behind the above-mentioned panel will be a small motor-generator, connections from which will be brought through the panel so that a low pressure for examination lamps and other surgical appliances will be immediately available. This motor-generator will be mounted upon a small truck, so that if necessary it may be taken to the wards and used in connection with wall plugs provided for the purpose. Intercommunicating telephones will be installed between the various departments, and electric clocks will be used throughout the building, the motive power for which, including that for the master pendulum, will be obtained from the supply mains through suitable resistances. Owing to the fact that a good many of the patients will be in single-bedded wards, communication with the nurses will be required from every bed, and, in order to minimise the staff required at night, the calls of each of the two ward floors will be switched on to ring upon the other, so that wherever the night nurse may be she will be within call of every patient. In order to avoid difficulty with the variation in resistance caused by switching in additional calls, the circuits will be fitted with special multiple contact relays enclosed with the bells and their indicators in dust-proof cases, the fronts of which are so constructed that the calls will be audible outside them.

Railway Electrification in Germany.—In a previous issue we stated that the electrification of the section Magdeburg-Halle-Leipzig of the Prussian State Railways had been deferred owing to the unfavourable condition of the Prussian finances. According to the *Elektrotechnische Zeitschrift*, the introduction of electric traction on the Berlin Stadt-und-Ringbahn has also been postponed for the same reason.

Institution of Engineers and Shipbuilders in Scotland.—The report of the Council for the session 1907-1908 states that the membership now amounts to 1,600, compared with 1,525 for the previous session. The Institution's new building was opened on December 8th, 1908. Including the site and furnishing, the total cost is expected to be about £30,000, and thanks are recorded to the large number of donors to the building fund. The surplus revenue for the session ending September 30th, 1908, was £639.

Imperial International Exhibition.—An Imperial International Exhibition is to be held upon the site of the Franco-British Exhibition at Shepherd's Bush, from May to October of this year. The exhibits will be classified and arranged in 18 groups, including a special group for electrical engineering, and others including civil engineering, mechanical engineering, textiles, chemical industries, &c. The exhibition will include the products and manufactures of foreign nations, their colonies and dependencies, in addition to those of the British Empire. The President of the Exhibition is Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., and the following gentlemen are among those on the General Committee:—W. H. Allen, Prof. J. A. Ewing, F.R.S., R. Hammond, H. Graham Harris, Sir A. B. W. Kennedy, F.R.S., W. R. Rawlings, Mark Robinson, C.P. Sparks.

Birmingham and District Electric Club.—Mr. G. T. Wood delivered his presidential address to the Birmingham and District Electric Club on January 16th. He pointed out that, although there were many institutions and societies for the discussion of the scientific side of nearly every subject, there were not so many which go far enough into the practical and commercial side, and it was to meet this want that their own club existed. He distinguished between "pure scientists," "applied scientists," and "commercial engineers," and pointed out how, no matter how skilful the manufacture of the article may be, even from the most scientific designs, unless it is handled in a sound, commercial way, it will in all probability be an absolute failure; and there is no doubt that in nearly every instance, however clever and complete the invention may appear, its finest points are brought out and developed, while it is nearing and after it has attained a commercial success. Several examples were mentioned to illustrate how important was the consideration of engineering problems from the commercial side.

WIRING OF BUILDINGS

A PAPER on the wiring of buildings was read by Mr. D. S. Munro, on Tuesday, January 12th, before the Glasgow Local Section of the Institution of Electrical Engineers. The author states that the purpose of his Paper is to show that no really good and cheap method of indoor wiring has yet been invented, and to elicit new suggestions and useful criticisms.

After brief mention of the early bare-wire systems, the author turns his attention to wood casing, of which he says, no other covering keeps the cables in so good a condition. Cables removed from wood casing after twenty years appear as good as when originally fitted—a fact due partly to the high quality of early cables. Wood casing also permits of easy inspection of wires and lends itself to additions and alterations without disturbing floors and skirtings of rooms above. The chief defect of casing is that damp with acids from concretes, &c., if unnoticed, may so saturate the wood that leakage and electrolytic corrosion affect the copper and its coverings and cause fire to occur. Yet there are fewer fires with wood casing than with other systems of wiring. But he asks the cable-makers how it is that small cables, even of the Association 2,500 megohm grade, break down so rapidly and inevitably when a little damp gets about them. Sometimes casing is embedded in plaster, but if this be done it must be well varnished, in and out, before fitting, and be left open until the plaster is quite dry. Wood casings are most often of American whitewood or of so-called cypress; but yellow pine, pitch-pine, teak, and the cheaper qualities of mahogany are all serviceable at times. Wire nails, but preferably iron or brass screws, are used for fixing casing, and brass nails always for capping. It is often useful to form cable casings in dado rails and picture or cornice mouldings. With plain or special casing thus carried round walls and fitted with plug sockets at intervals, one is at a loss sometimes as to the best method of getting from the casing to central roof-points or brackets. Were it not for dust troubles, a quite neat arrangement is to loop boldly out or down from the sockets on wall casing with "flexible" of colours to suit the rooms. Where flexibles are not used other methods of getting from wall to roof must be devised. In crossing mouldings, the plan has been tried of cutting away a short section and reforming it with grooves of special plaster behind. Or again, a carefully designed metal conduit bracket has been adopted as a cornice crossing. The more usual method is to terminate the crossing on either side of the plaster mouldings, and connect by a concealed tube. These short lengths of connecting tube are few and short on a well-planned job. When they are of metal, usually compo or zinc, it is necessary to test that they are free from contact with other pipes or structural metal. They are better not "earthed."

In the "Continental" system of lighting, flexible wires are spirally twisted together, and fastened to walls and ceilings by means of small stud or ring insulators. The mains and sub-mains are generally of ordinary V.I.R., taped and braided cable, led in thin brass tubing with insulated lining, or in wood casing. The sub-circuits are entirely exposed, except where wires pass through walls or ceilings, where tubes are introduced. The wires are so small that their presence is not unduly obtrusive, and this is specially the case if the braiding is coloured to suit the walls. Joints should generally be made in china terminal cases, but if care is used it is possible to make a mechanically strong junction btween two lengths of double flexible by fixing the joints about a foot apart, the intervening twistings giving the necessary strength. This is, perhaps, the cheapest of all systems to install, as the accessories required are few and simple, and the time required for erection little. Where the voltage is low, and temperatures are equable, five years may be counted about the average life. It is strongly advocated by some, but the author considers that its general adoption would ultimately prove harmful. This system has a powerful supporter in Professor Schwartz, whose historic Paper on "Flexibles" (*see* ELECTRICAL ENGINEERING, Vol. I., page 719) surprised many engineers, showing, as it did, that common flexible would withstand an astonishing amount of ill-treatment.

Where an installation is fed from a private source the concentric system may be used, often with economy, safety, and convenience. But few supply companies having an earthed mid. will connect to such an installation, as there is likelihood of "earth" complications. A cheap modification of concentric wiring consists of an insulated conductor threaded, together with a bare copper wire, into ordinary gas compo. tube—the bare wire assisting the compo. to convey the return current. This is cheap, and may yet do good service if very well planned and fitted. Lead-covered wires, both single and multiple, are the right things to use in many situations, chiefly in parts of ships and mines, or where exposed to steam, as in factories, and on the outside of buildings. At first sight it would seem that lead-covered cables would form an ideal method for the general interior wiring of buildings, but in the writer's experience no other system has proved so troublesome. It is difficult to avoid blow-holes when sealing up lead joint-boxes, and to avoid roasting the interior joints. These defects are got over by the Key Engineering Co., who make cast watertight boxes fitted with block-joint terminals, and having brass clamping glands which grip the sheath, and so make soldering unnecessary. The resistance of lead is greater than that of iron, and therefore it requires earthing at more points. Even then, as the lead sheathing is liable to crack, sections of the covering in time get disconnected from "earth." When there is an accidental "short" the lead melts as readily as the fuse. Rats and mice appear to prefer lead to casing. In some situations where dry rot or ammonia helps the formation of lead acetate, the covering gradually crumbles entirely away. The chemical action must be somewhat complicated, as the rubber, and even the copper, are affected in such cases and become quite brittle. Great care is requisite in treating open ends to reduce "creeping."

Heavy brass and copper tubes, unless they are utilised as conductors, are too expensive to be commercially practicable. Some engineers now use light brass conduit for general housework. It is of small bulk and easily run behind strapping and plaster. It is not unsightly if run on the surface; but the soldered bonds may be apt to prove susceptible to electrolytic action, and the tube itself is easily injured. A zinc tube system has been used. The tube had to be very carefully run to avoid contact with other metals, and having simply a close seam it was not watertight, although, with the seam always underneath, water seldom gave trouble. This tube has the merit of being difficult to corrode, and it keeps the rubber cables in good condition. Gas-barrel, when carefully rimered, has some advantages over the steel tube now in common use. Wrought iron does not begin to rust so soon as the special steel used for conduits, and the action does not spread so rapidly. Thin steel split enamelled conduit is too light to carry a thread, and the couplings are necessarily of sleeve form. These allow of very quick erection, however, and the system is useful in places where voltage is low and electrical continuity of little importance. The tube is not suitable for burying in cement or plaster, however, and when laid beneath a floor must be well out of reach of possible nails. The fact of the couplings being unscrewed is at once the strong and the weak part of the system. Much time is lost on an installation in screwing, and with the object of obtaining electrical continuity while retaining the advantages of unscrewed conduit, many forms of coupling have been brought out. Continuity is attained by scraping, compressing, or pinching by means of various devices attached to the coupling. An adaptation of the light class of steel conduit with unscrewed coupling has been lately put in the market by the Key Engineering Co. (*see* ELECTRICAL ENGINEERING, Manchester Exhibition Supplement, page 42).

Screwed steel conduit is generally supplied stove enamelled to the contractor. The enamel is of an insulating nature, and is of many qualities, some of it being so ill applied that it comes off in flakes when the tube is bent. Even the most tenacious enamel, however, is removed where the conduit is gripped by a pipe vice; it is also rubbed off where the tube is clasped by saddle or crampet. Again, the screwed ends of conduits are free from enamel, and as the couplings do not always cover the screws, there are many places left open to the action of rust. After the conduit is in position it should, therefore, be gone over carefully and these weak places painted. Screwed steel conduit is made by three methods—solid-drawn, brazed and welded. Solid-drawn tube is the dearest, but is sure to have a smooth bore owing to process of manufacture. In brazed conduit the sheet steel is cut at an angle so that when the tube is formed a V-shape seam is left; this is then filled in with spelter and brazed. To be successful the edges must be perfectly bright and the heat very carefully and evenly applied. Users of this class of conduit occasionally find gaps in the brazing and sharp ends of spelter inside the bore, also chemical and electrolytic action cause the spelter to crumble away when the conduit is run in unsuitable places. Welded conduit is cheaper than the previously mentioned forms. Occasionally the weld is slightly thicker than the rest of the wall of the tube, but this is not a serious disadvantage, though it may affect neat bending. This variety is generally watertight, but one comes across imperfectly welded lengths, where the seam is open, and sometimes, what is worse, one of the cut edges of the metal is bent inwards, presenting a sharp ridge to the interior wires.

Joint boxes, which are generally malleable castings, constitute

Digitized by Google

a not inconsiderable item in the cost of an installation. Many are much too small for their purpose, and it is impossible to get enough slack wire to enable the joint to be pulled out to be soldered properly. Many boxes contain china connectors, intended to replace insulated joints. These have the advantage of reducing the time required to make connections, and they also facilitate testing separate lengths of wire; but they tend to reduce the insulation resistance owing to surface leakage across the china surfaces. Few engineers would defend unsoldered joints, yet many seem to consider that these terminal blocks represent the highest class of wiring work. In most patterns of china terminal boxes there is little space between the brass terminal and the metal side. It is therefore necessary that the rubber be brought hard up to the brasswork, and rubber soon deteriorates in contact with brass. This action would be lessened if the terminals were tinned.

With regard to the method of distribution, some engineers appear to consider that the fewer lamps per branch-circuit the better. In a most unimportant city forty odd miles east of Glasgow, four lamps per circuit are frequently specified. The result is a great increase in the length of conduit and wiring, more cable to maintain, more risk of breakdown, and more cutting up of flooring joists, &c. The three-ampere limit of the Institution rules is a good maximum for ordinary buildings. There are many buildings—churches and public halls for example—where a large current per branch-fuse is often advisable. There seems no need for the wholesale adoption of the looping system and the entire abolition of insulated joints. Where looping is employed extensively, it means a considerable addition to the amount of cable required, and to the number or size of conduits. More boxes are generally required on a looped circuit than on a jointed one, because it is usual to carry the tube in loop round the circuit and take short branches to the various light and switch-points from tee boxes.

Conduits are usually run over joists, which are grooved to receive them, and often injured by over-cutting. To avoid cutting they are sometimes run under joists, but they are then much less accessible for repairs and alterations. In surface work it is often advantageous to keep the tubes sufficiently clear of wall to permit of repainting all round. There are distinct advantages to be gained by so fitting the tubes that they are moderately well insulated from "earth." When this is done it is possible to test the continuity of all tubes, and to test also their freedom from contact with other metal. To facilitate these tests there ought to be a sealed disconnecting box in the earthing wire. If a resistance in the earth wire is to be used, such a box would be a convenient point for its connection. This proposal might be extended to the circuit fuses; thus, on the occurrence of a short on a branch wire, a resistance might be inserted in the circuit by a simple electromagnet arrangement; but possibly a low resistance arranged for high self-induction would be simpler, and could be fitted in the distribution box for each pair of fuses. Such an appliance would tend to reduce the flash in a short-circuited lampholder, for example, as well as lessen the injury to fuse-box carrier or cover.

In the plainer class of work outlet boxes are not used, the hardwood blocks being made to serve instead. The conduits, fixed before plastering is complete, and having their ends protected by screwed wood nipples, are terminated as near as may be to the position of future blocks on surface. This, however, leaves portions of the wire exposed. A much better plan is to fix in a plaster-board, so shaped that it not only provides a support for future switches or their blocks, but acts also as a holder for tubes and wires. The holes for tubes should be so bored that they hold ends firmly, and also act as protecting nipples against possible sharp edges. Wood-box outlets have this advantage over metal boxes, that it is usually easier to get high insulation, and they are also more readily adapted for varying depths of plaster and types of building construction. Except in concentric work metal fittings are perhaps better on the whole to be insulated from earth. For cheaper work the conduit under floor above an electrolier is bent down vertically and terminates in back of wood block on surface of ceiling. This block is screwed to wood fixture provided for it, and fixed between joists. The ceiling plate of the fitting is made hollow to provide space for joints or for china connectors. The plate, which supports the fitting, is then screwed direct to the block by wood screws. A common modification of the above method is to fit a tube projecting an inch or so below the ceiling and to screw a heavy brass hook thereon on which the electrolier is hung. The hook has an exit with insulated nipple for wires. Where this is adopted the tube requires support under floor above, which is best provided by means of a screwed flange resting within an asbestos-lined wood box. As the conduit merely enters or passes through this box an alternative position for joints is thus provided, and the fitting is insulated.

With regard to testing, the author considers that tests between outer and mid, or positive and negative, ought to be made and recorded with the same care as that between cables and earth. Insulation tests are usually only tests of the surface leakage on switch, fuse, plug, and holder surfaces, and a good or bad test is more a test of the dampness of the building than of the quality of the work, yet much may be done to improve the test by attention to such details as have been described, and to the proper treatment of coverings at cable ends. Turning to the subject of fire risks, the author quotes the case of a large city, having some 17,000 consumers of electricity, in which there were only thirty-six fires due to contact with gas pipe within the last seven years. Of these, only two were with casing; one was caused by a nail driven through wall-casing and gas-pipe, and the other by a gas-pipe lying on wet casing in a basement. Lead-covered wire fires are much more numerous than they ought to be, considering the small portion of wiring done on this system. Of the twenty conduit fires, sixteen were in slip-joint systems, and the remainder in screwed conduit. No data are obtainable as to the earthing of these screwed tubes, but as a matter of fact, if they are in direct or indirect contact with gas-pipe, earthing makes little difference in fire risk. Besides the above fires due to contact with gas-pipe, there were sixteen other "electrical" fires during the same period due to other causes. In view of these figures, it will be admitted that the fire risks of electrical wiring are small. With regard to the relative cost of systems, there is little difference in cost between conduit and casing. Lead-cased wires are cheaply fitted, and they have their advocates. The current prices obtainable for wiring are hopelessly inadequate to provide for the best class of work. The very best conduit work cannot at present be done at a cost of less than 2Cs. per light-point for branch tubing and wiring only, including outlet boxes. In some cases 30s. would do no more than cover cost. Yet carefully specified work is taken every day at 10s. per point, and often for much less. It is quite possible that there will be a return to lower consuming voltages coincident with the development of high-tension transmission. With pressures of 25 to 100 volts the wiring precautions can be very materially reduced, and cheap methods of wiring would have a fair chance notwithstanding the increased size of indoor cables. Whether present pressures be changed or not there is a demand for a cheaper system of wiring. Iron or steel conduit has not much in its favour, except that it is a little more difficult to pierce by chance nails, and is impervious to the attack of rats and mice. Its thickness of metal also promised to confine the flash of a short circuit, although when the flash occurs it is usually burned through. But it is expensive and intractable in erection; it requires much space and cutting up of building fitments. It is haunted by water of condensation, and will, sooner or later, give much trouble through rust. If wiring must be concealed, what is wanted for branch wires, and of which we now chiefly speak, is cable, with its metallic protection complete, manufactured in long lengths and delivered in coils, and soft enough to unwind, bend, and straighten easily. The continuous metal covering could be used as mid-wire in town work, or as, say, negative in isolated work. With such a metal covering, enamelled, run in dry places and on insulating studs in damp places, the leakage risk would be small, seeing that the external metal would be so nearly at earth potential. The electrolytic trouble which threatens a concentric outer would be hindered by the enamel, &c. On account of rats and mice, and for conductivity and durability, copper should be a good material if well enamelled with an elastic mixture. But whether or not we can get a conduit cable suited for pulling in anywhere, or of being carried out and in over varying surfaces, it would certainly be a convenience if architects in designing buildings would provide better paths for electrical conductors. Many of the new fireproof buildings are planned as if to make the running of wires or pipes impossible.

Electric Smelting of Iron.—Some works have recently been opened in Flekefjord, Norway, for carrying out on a commercial scale a new electrical process for the reduction of iron ore and the production of steel. If successful, the works will be enlarged, and the manufacture of steel plates on an extensive scale undertaken. Power is obtained from a local waterfall.

Death from Electric Shock.—An inquest was opened at Wakefield on Friday concerning the death of James Platt, a miner, who was killed in the explosion at the Ackton Hall Collieries, Featherstone, on the 19th inst. A statement made by deceased after the accident was to the effect that when switching off the electric fan an explosion occurred which knocked him down. He also stated that the fan was in proper working order. As the Electrical Inspector of Mines is making investigations into the accident, the inquest has been adjourned.

DEVELOPMENT OF THE LANCASHIRE ELECTRIC POWER CO.'S SYSTEM

DURING the past year or two, the system of the Lancashire Electric Power Co. has been developing at a rapid rate, and there are now a large number of works on its mains benefiting by the economy and convenience of electric power supply. Fig. 1 is a map showing the portion of the company's area in which supply is being given up to the present; it does not represent the whole district in which the company has power to supply, but it is seen that the mains already extend a considerable distance from the power station at Radcliffe. Unfortunately the company is not allowed free entry into the larger towns, which are shaded in the map, and in only a few instances has it been able to supply these by special arrangement with the local authority. In the map, we have marked the routes of the high-tension feeders, the position of the large consumers or sub-stations, and the approximate number of kilowatts of the supply in each case. The consumers include various engineering works, collieries, textile mills, print works, bleaching and dye works, and local authorities who

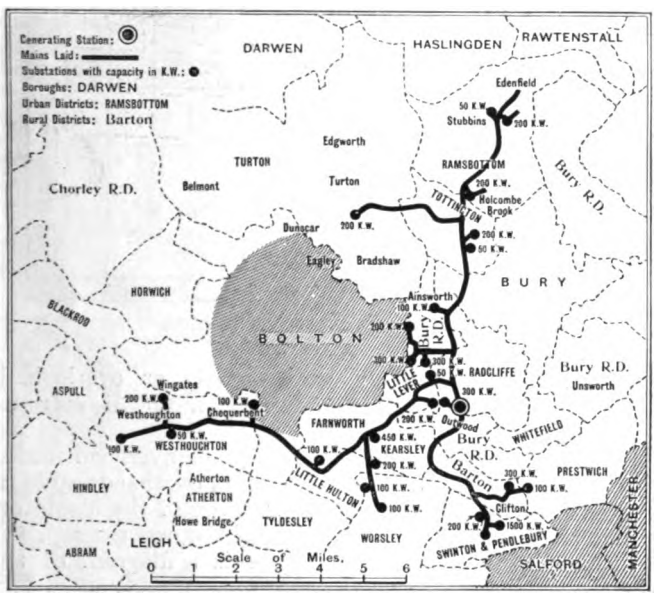

FIG. 1.—MAP SHOWING ROUTE OF FEEDERS, AND PRINCIPAL CONSUMERS AND SUB-STATIONS.

take power "in bulk" from the company and distribute it for lighting. In one or two cases, the company have taken over the Provisional Orders from the local authorities and do the distributing themselves.

The generating station at Radcliffe now contains four 2,000 kw. B.T.-H. Curtis turbines of the vertical type, with the footstep bearing, in which water pressure is used to take the weight of the shaft and rotor. It may be mentioned incidentally that no trouble has been experienced with these machines, and that the bearing is practically frictionless; it is actually possible to turn the rotor by hand, and the machine will run for nearly an hour with its steam shut off, so that it is necessary to leave on the excitation when shutting down. The works obtain their coal directly from a railway siding by means of automatic conveying plant actuated by the weight of the coal itself, and ample circulating water for the condensers is obtained from the River Irwell. The consulting engineers for the scheme were Messrs. Lacey, Sillar & Leigh, acting in conjunction with Mr. H. F. Parshall, who was responsible for the power-house, and is now chairman of the company. The original cable and overhead work was carried out by Callender's Cable & Construction Co., under the supervision of Messrs. Lacey, Sillar & Leigh, but at present all new work is being done by the power company itself. Mr. C. D. Taite, the engineer and manager, succeeded Mr. R. L. Gamlen

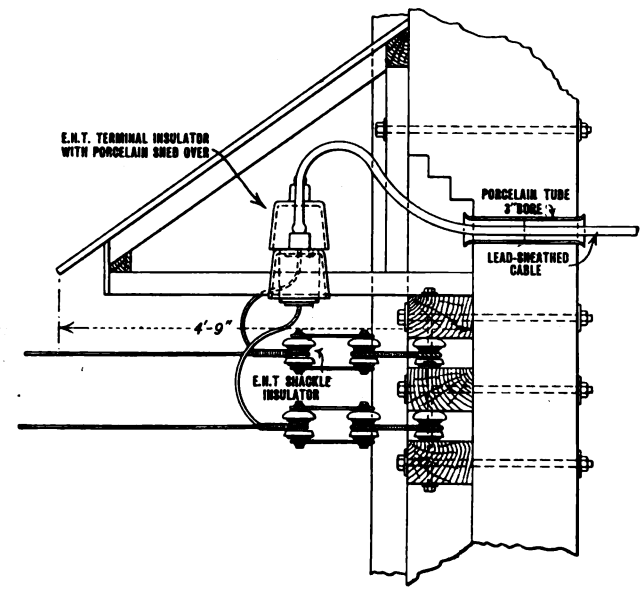

FIG. 2.—LEADING OUT AT STATION.

about two years ago. We are indebted to Mr. Taite for devoting a whole day to showing us several of the recent developments of the system, and for furnishing us with detailed information, drawings, and photographs.

Power is generated at 11,000 volts, three-phase, 50 cycles per sec. Cables are run from the generators under the floor of the engine-room to remote control switches and 'bus-bars in brick cubicles, according to the accepted modern practice, but all the feeders leave the station overhead. The method employed is shown

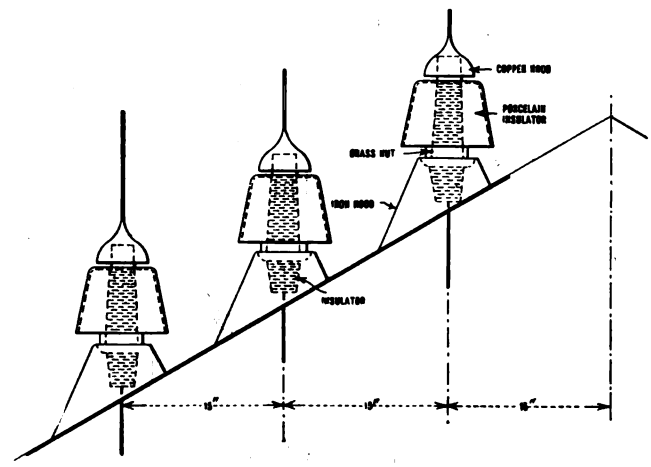

FIG. 3.—LEADING IN AT THE SUB-STATIONS.

in Fig. 2, which is self-explanatory. "Multi-gap" static dischargers of the British Thomson-Houston Co.'s make are employed both at the station and at the sub-stations, and no trouble has been experienced during thunderstorms. It is easier now to obtain wayleaves for overhead mains than it was a few years ago, and as also a portion of the E.H.T. network is

Digitized by Google

in populous districts, there has been much cable work. At present there are about seven miles of overhead route and 30 underground. Wade's creosoted "A"

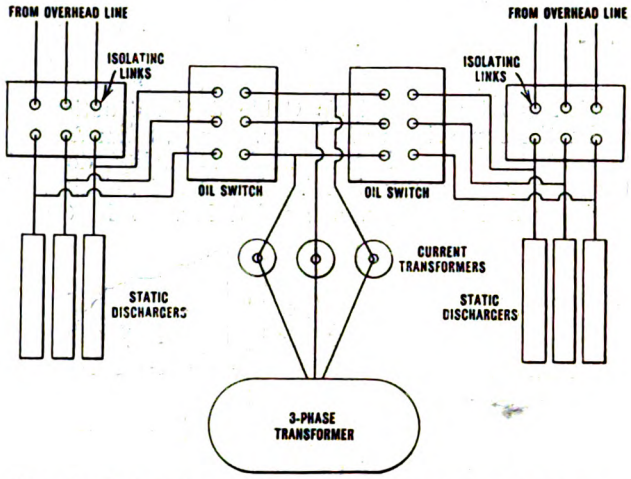

FIG. 4.—DIAGRAM OF E.H.T. CONNECTIONS IN SUB-STATION.

poles are employed throughout for the overhead lines, the size being what is known as 9 in. poles. Where telephone wires have been put up, a separate pole line

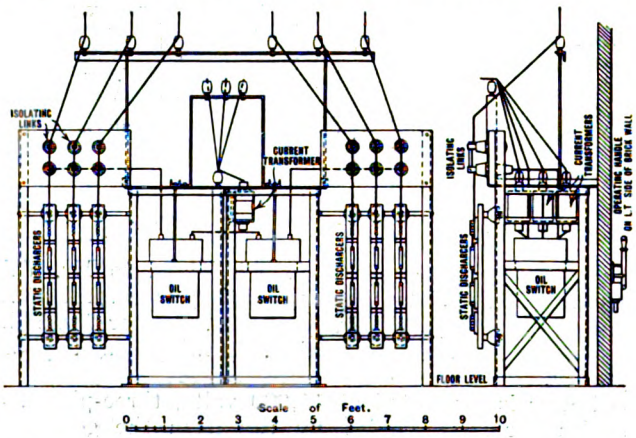

FIG. 5.—ELEVATION SHOWING POSITION OF APPARATUS IN SUB-STATION.

has been erected for them. The E.H.T. lines have therefore not been revolved, and the whole arrangements are extremely simple.

It is also the simplicity of the sub-station arrangements that is their most interesting feature. They are divided into two portions by a brick wall without a door, and the E.H.T. side is thus kept in a separate locked chamber, accessible only to the power company's officials. In this no attempt has been made to protect the live conductors and apparatus, but the opposite policy has rather been followed; that is to say, on opening the door and passing through another door in an expanded metal screen, the live conductors are so prominently in view and within reach that the

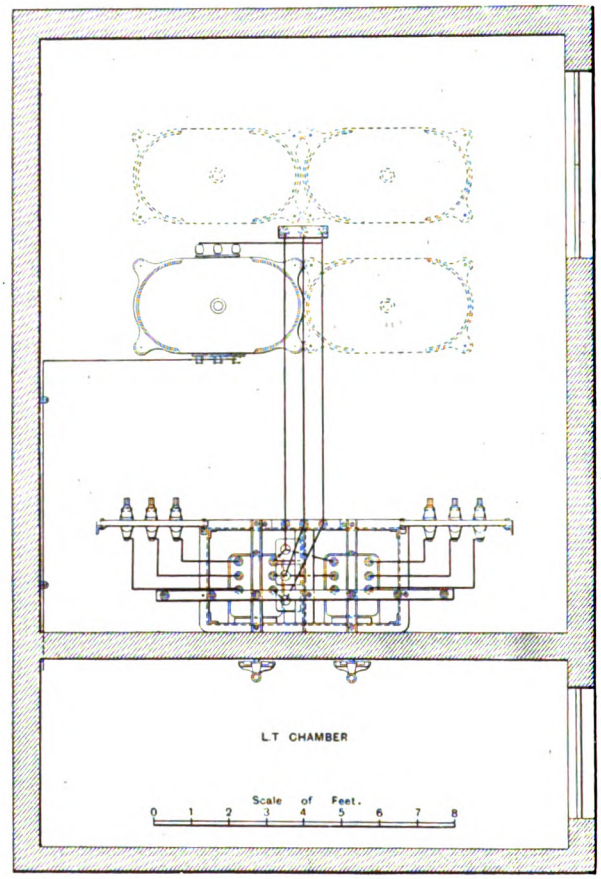

FIG. 6.—PLAN OF SUB-STATION.

danger cannot possibly be forgotten or overlooked. The arrangement has the further merit of extreme cheapness.

Fig. 3 shows the manner in which overhead mains are led into the sub-stations. The overhead cable is sweated into a copper hood at the top of the insulator, and the leading-in cable is brought down through the inside of the insulator. Fig. 4 is a diagram of the

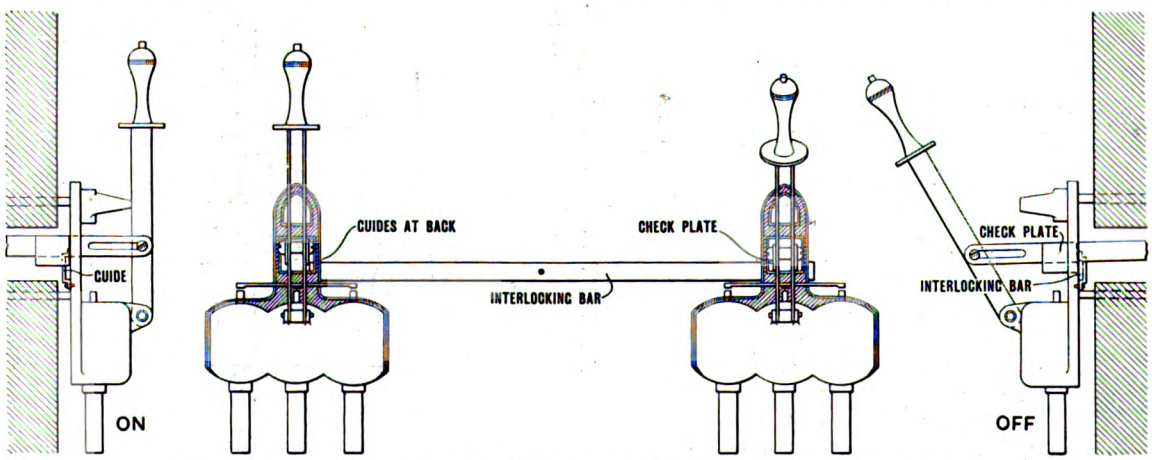

FIG. 7.—INTERLOCKING GEAR ON HANDLES OF OIL SWITCHES IN SUB-STATION.

E.H.T. connections in the sub-station. Fig. 5 gives two elevations showing the position of the isolating links, spark-gap dischargers, and the oil switches, and Fig. 6 is a plan of a sub-station. Figs. 5 and 6, although necessarily diagrammatic, are to scale so far as the

Digitized by Google

position of the apparatus is concerned, and the floor level is shown in Fig. 5, so that the actual arrangement of the sub-station is well brought out. It should have been mentioned that all the feeders, without exception, are duplicated. Referring to Fig. 4, the three lines which constitute each feeder are connected through isolating links directly to the oil switches, and branches are taken to the static dischargers. The connecting wires are all of bare copper, and, except for the dotted lines in the front elevation of Fig. 5, which are behind the supports, all are fully exposed. The handles of the oil switches are on the L.T. side of the brick wall, and are so interlocked that only one of the two switches can be on at the same time. The locking arrangement is shown in Fig. 7, from which the trip-gear has been omitted so as not to complicate the drawing. The three wires connected to the transformer side of the switches, which represent the 'bus-bars, are connected through current transformers (for actuating the trip coils of the switches) to the three-phase transformer, or transformers. In the sub-station shown in Fig. 6, there are four transformers banked, but a precisely similar arrangement

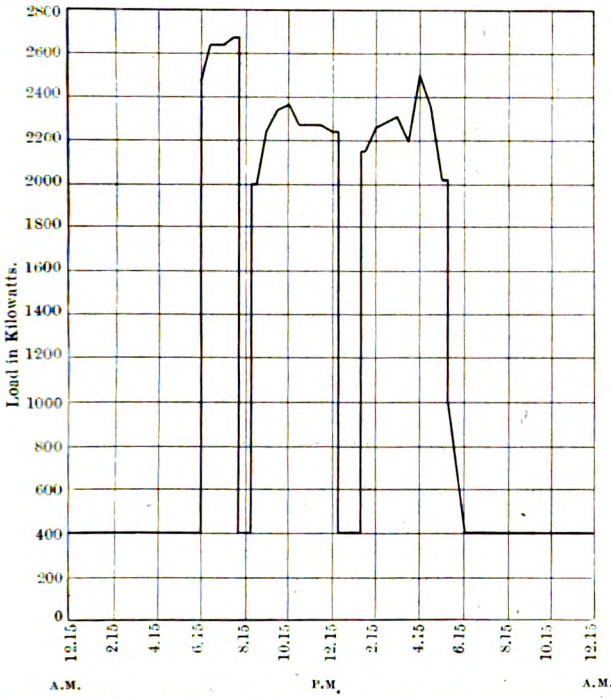

FIG. 8.—A TYPICAL LOAD CURVE (UNITS GENERATED DURING THE 24 HOURS, 29,390).

is employed in the case of sub-stations with one transformer (as in Fig. 4) or two transformers. Three-phase oil-cooled transformers have been employed throughout, and a standard set of sizes has been chosen, viz., 50, 100, 200, and 300 kw.

Fig. 8, a typical load curve of the total load on the generating station, shows how it is possible to charge a low price for power supply in the district. From 6.15 in the morning to 5.30 p.m., the load does not drop below three-quarters of full load except at breakfast and mid-day dinner time. The increased load due to lighting in the early morning and evening are clearly seen, and except for these variations the load is almost constant during working hours. The sharp drop at 5 o'clock shows that the amount of overtime now being worked is inappreciable. There is a steady load during the remaining time, part due to ventilating and pumping, but a considerable proportion also, it must be feared, due to the magnetising current in the sub-stations. Pumping loads, however, can frequently be arranged for a few hours a day in such a manner that the times are at the option of the power company, and by this means, no doubt, the level parts of the curve may possible be raised. Still, a sharp rise and fall, each at a definite hour every day, makes a more economical load to work to than would be an ordinary combined lighting and power station load with an equal average load factor, in which the

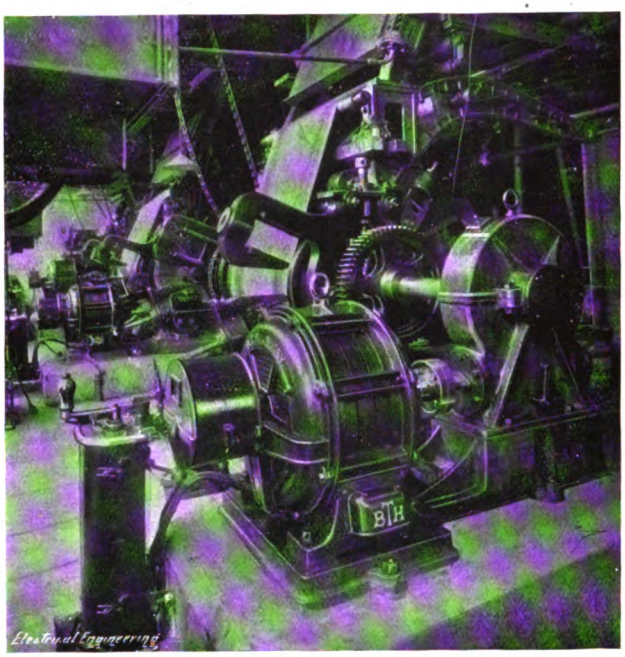

FIG. 9.—25 H.P. MOTORS DRIVING CALICO PRINTING MACHINES.

shape of the load curve would vary from day to day. On the Lancashire Power Co.'s system, the ratio between the maximum load on the station and the number of kilowatts representing the total connection is also a good one, the former amounting to about 3,000 kw. and the latter about 4,200 kw.

In the limits of a short article, it is impossible to

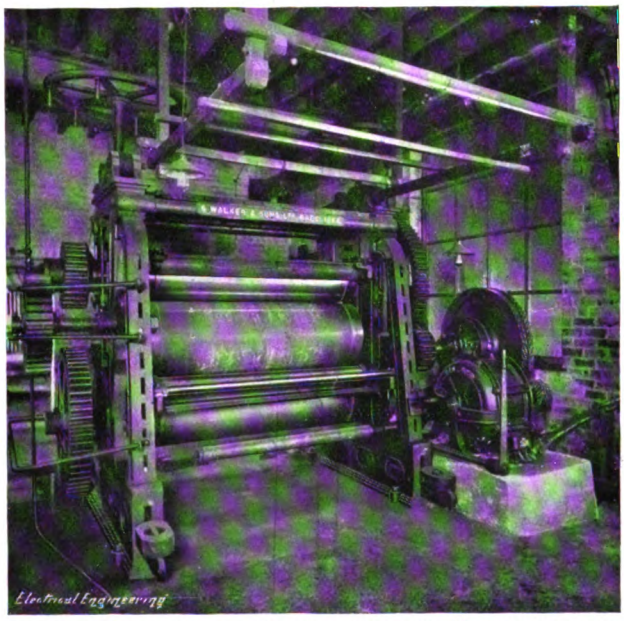

FIG. 10.—40 H.P. MOTOR DRIVING FRICTION CALLENDER AT THE WOODLEY PRINT AND DYE WORKS.

give a complete account of the applications of power by the various consumers. We add, however, a few photographs of some of the more interesting examples. Fig. 9 shows three motor-driven calico printing machines at Messrs. Schmidlin, Brown & Co.'s works, part of an installation of 370 h.p. The motors in this case are rated at 25 h.p. each. The former practice at such works was to drive each of the machines by

Digitized by Google

a small diagonal engine, which, of course, necessitated long lengths of wasteful steam-piping, and, in addition, the average diagonal engine is very inefficient in steam consumption. Another advantage of replacing the engines by motors is that in "making ready" before the actual run of the machine, the motors can be made to turn slowly by means of regulating resistances, while with engines it was necessary to bar them round for making the preliminary adjustments. The saving in time is very great, and it has also been proved, in cases where tests have been possible, that the work done during the actual run is accelerated on account of the perfectly constant speed and steady drive. With the small steam engines it is necessary to set the average speed lower than the maximum that the material and process would bear, in order to allow for the possible increases due to bad regulation or variations in the demand for steam from the comparatively small boiler plant.

Through the courtesy of Mr. Hodgson, one of the partners of the Woodhey Print & Dye Works, we were privileged to inspect these works, in which motors have replaced the old diagonal engines. Three large printing machines are there driven by 17-h.p. B.T.-H. induction motors, and the arrangement of the motors and controller is similar to the case illustrated in Fig. 9. Slip-ring induction motors are employed, and large resistances in the rotor circuits enable sufficient speed regulation to be carried out, so that with the help of the gear on the machines themselves, nice adjustments of the speed are possible. In these works, the "stentors" for stretching the material are also electrically driven, and the fans for the hot-air blast that is used in connection with these machines are likewise worked by motors; a 10 h.p. motor is sufficient for the fans for two large stentors. A 40-h.p. motor, driving

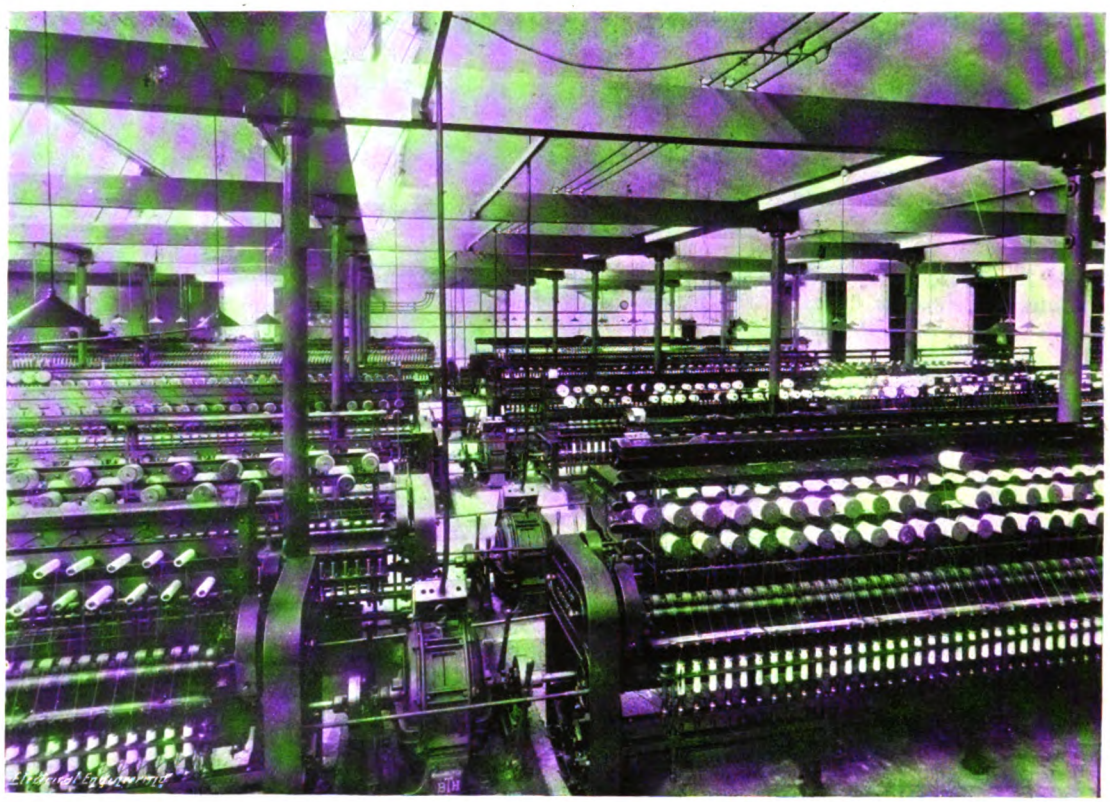

FIG. 11.—MOTOR-DRIVEN DOUBLING SHED.

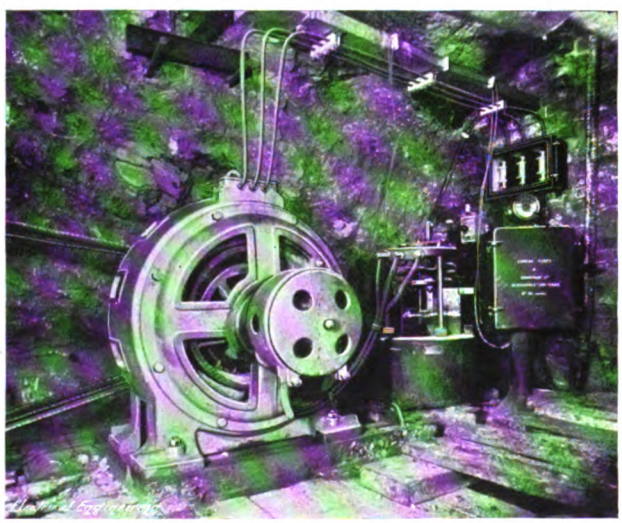

FIG. 12.—80 H.P. MOTOR DRIVING THREE-THROW PUMP IN LADYSHORE COLLIERY, LITTLE HULTON.

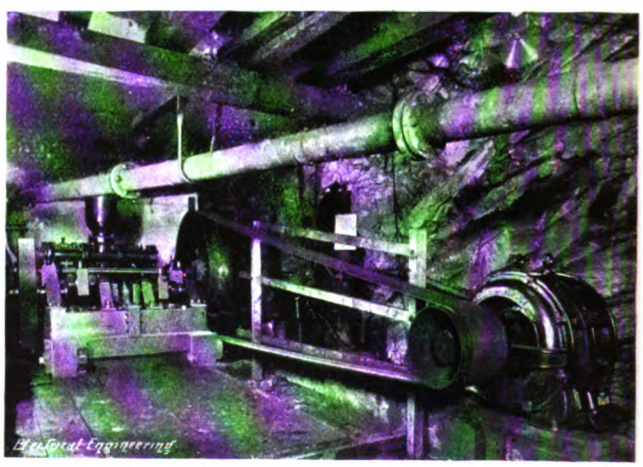

FIG. 13.—50 H.P. MOTOR BELTED TO THREE-THROW PUMP AT STOPE'S COLLIERY, LITTLE LEVER.

Digitized by Google

a friction callender at these works through helical spur gearing, is illustrated in Fig. 10. In this case a star-delta starting switch is employed; the method mostly adopted. A large open soaking and driving machine is also motor-driven, and in all the electrical installation aggregates 250 h.p. Actual figures as to the saving in power costs are not yet obtainable, but we are able to state that, although steam has still to be employed for heating and boiling, necessitating the maintenance of some of the old boiler plant at the works, the economy from changing from steam to electric driving has been very marked.

This installation, as several others on the power company's system, has been wired by the Lancashire Power Co. itself. Plain surface work is employed, for the most part rubber-covered wire held to the walls and ceilings by porcelain cleets. The current is taken from a static sub-station near the works at 400 volts three-phase. In such cases a five years' hire-purchase arrangement is made for the sale of the wiring, motors, and accessories.

In these works, the print works furnish the chief portion of the electrically-driven machinery. At the Mount Zion bleach works, on the other hand, owned by the Bleachers' Association, a 250-h.p. motor has been put in to replace a slow-speed horizontal engine, and it has been found that the work is done much more expeditiously. Careful records are being kept, so it may be hoped that some comparative figures of costs will be obtainable eventually.

Fig. 11 shows a motor-driven doubling shed belonging to Messrs. Faulkner & Co., of Worsley. Here the plant was laid down for electric drive from the outset, and textile machinery experts will recognise that the disposition is an eminently practical one. The motors, which are rated at 15 h.p. each, are directly coupled to the doubling frames. The shed will eventually contain about 36 frames. As is seen in the illustration, the method of wiring is as simple as in the previous examples.

Although collieries form at present a comparatively small proportion of the company's load, we give two illustrations to show the use of motors in the pit under conditions where the employment of other methods of driving would be difficult with equal economy and adaptability. Fig. 12 represents an 80-h.p. Scott & Mountain motor, which drives a three-throw pump at the Ladyshore Colliery, Little Lever. The cabling and wiring and the auxiliary apparatus are clearly seen. In Fig. 13 a 50-h.p. motor is shown, belted to a three-throw pump at Stope's Colliery. Up to the present, no electrically-driven winding plants have yet been put down for connection to the company's mains, but there is a certain amount of ventilating and haulage as well as pumping.

The Lancashire Electric Power Co.'s system is, as has been seen, particularly interesting by the large diversity of the applications of electric power in the district, and the economical methods of generation, transmission, and distribution should lead to a rapid development of the company's undertaking in the near future.

ELECTRIC POWER AS A COMPETITOR TO SUCTION GAS

THE following letter has been sent to the engineers of the leading electricity supply undertakings, by Mr. F. L. V. Mathias, Borough Electrical and Tramways Engineer, Warrington, with a view to obtaining information as to the results of competition between electric driving and independent suction gas plants:—

It appears that electricity has a competitor, although probably only a temporary one, in suction gas. It would be very useful, when having to deal with wobblers in favour of suction gas, to have a list of people who have tried suction gas, and found it wanting. If you have any such people in your neighbourhood who have thrown out suction gas plant, I should be very glad if you would let me have a list of them, with any particulars relating to the case which might be useful. I would forward you copy of replies received.

A large number of replies have been received, extracts from some of the most interesting of which are given below:—

Battersea.—Have several firms anxious to adopt electricity in place of suction gas, but are unable to dispose of suction gas plants.

Fulham.—Obtain all new and extension work against suction gas. Replaced a large suction gas plant, consisting of two 60 h.p. sets with two-phase motors.

Hackney.—State that their charges, which are £1 per kw. demanded per quarter, and ½d. per unit with 20 per cent. of allowance for lighting purposes, enable them to be proof against suction gas.

Shoreditch.—Have displaced a large suction gas plant of three 70 h.p. engines by electricity.

Stepney.—Have displaced two suction gas plants by electric motors.

St. Marylebone.—Have been successful in competition with suction gas on several occasions.

St. Pancras.—Have displaced a suction gas plant, consisting of 30 and 40 h.p. engines, which had been running two years.

Barrow-in-Furness.—State they do not fear any trouble from competition with suction gas, as all the firms who were considering the point put in electric motors in preference to suction gas.

Aberdeen.—Have acted as stand-by of one plant.

Accrington.—Have replaced a suction gas plant which had superseded their electric supply for a period of six months. Another suction gas plant they are stand-by to, the owner states that without capital and maintenance charges the cost is over 1d. per unit.

Bedford.—Know of two suction gas plants in the town; one firm wished to have electric current, but were too far away from the mains; the other firm failed.

Blackpool.—Have displaced a 100 h.p. suction gas installation for electric motors.

Blackburn.—State that suction gas, which a few years ago threatened to be a serious competitor, has lost its hold in Blackburn.

Bolton.—Do not consider suction gas plant is likely to be a strong competitor to electricity.

Bradford.—Have received an inquiry from a firm who use suction gas, who state that electricity at 1d. is better than suction gas, and as soon as the plant can be disposed of they intend taking Corporation supply.

Burton-on-Trent.—Have two suction gas plants in the town; one is now being run on Town's gas, the other firm express a desire to put in motors.

Cardiff.—Have displaced a suction plant by motors.

Colchester.—State that a large engineering firm had a suction gas plant of 150 h.p., but after two years' running the firm paid for a large distributor, and took current from the Corporation at 1d. per unit in preference.

Croydon.—Have installed two large electric motors in place of a suction gas plant.

Darlington.—Have a firm who installed suction gas plant, but state there is no saving effected by using suction gas as compared with Town's gas; this firm put down electric motors for all their extensions aggregating over 100 h.p.

Dewsbury.—Regained a firm who had deserted for suction gas. Another firm abandoned a suction gas plant, and states that electricity at 1d. per unit is considerably cheaper than suction gas.

Doncaster.—Are acting as a stand-by to a firm which has a suction gas plant.

Dudley.—Have replaced a suction gas plant of 40 kw. The firm in question state that current at 1d. per unit, although it has to be converted from D.C. to A.C., is cheaper than the suction gas plant. Also state that they have several motors installed with firms using suction gas plants, which are earning a fair revenue.

Dundee.—Have displaced a suction gas plant by motors; the firm state that electricity is found to be 10 per cent. cheaper. The following figures are given:—Plant, 6 to 15 h.p.: coal bill, £20 per annum; attention, £27; interest on capital £12 10s.; depreciation, £25; total cost per annum, £34 10s.

Goran.—State that a boiler-making firm tried a suction gas plant, but installed electric motors in their new works. A wire-weaving works replaced a steam engine with suction gas, but put electric motors in their new works. A constructional iron works put in a gas engine, but were threatened with prosecution for nuisance, and put in a motor.

Digitized by Google

Greenock.—State that while the Corporation have no less than 4,900 h.p. of motors connected to its mains, there are only one or two very small suction gas plants at work. Competition with suction gas was threatened two or three years ago, but investigation by largest electricity consumers did not substantiate gas claims—conclusion formed that electricity at a penny per unit could not be improved upon for power purposes. Displaced a suction gas plant of 100 h.p. at a boiler works owing to the breakdowns by a motor of 80 h.p.

Grimsby.—Report a saw mill with a very variable load in their district have abandoned a suction gas plant.

Halifax.—Have displaced a 25 h.p. suction plant in an engineering works, and a similar-sized plant at a cotton spinner's, for electric motors.

Harrogate.—Have been able to prevent suction gas being installed in preference to motors in several instances.

Keighley.—Report that several of their consumers have been into the question of suction gas as opposed to electricity, and are quite content with electricity.

Leeds.—State that a steel company have discarded a suction gas plant for electric motors.

Luton.—State that an engineering firm abandoned suction gas for Town gas, and finally gas altogether, for electric motors, power 100 h.p. Another firm is making its extensions in electric motors, although they have a suction gas plant on the premises. Another firm tried suction gas in place of electric motors, but find it costs more than original electric.

Maidstone.—Have superseded a large gas plant of 200 h.p. for electric motors; the firm in question state that they are making a considerable saving by using electricity at 0·9d. per unit.

Middlesbrough.—Obtained the largest ship-yard in competition with suction gas, after very close inquiries had been made.

Rotherham.—Have recently connected a timber merchant to the mains, who has made the practical comparison of suction gas *v.* electricity in two other towns.

Sheffield.—Have displaced two suction gas plants in large works run by men with engineering abilities, for electric motors.

South Shields.—State that a firm of boiler makers put in large suction plant and two engines, one driving line shafting, the other a dynamo for 250 h.p., in motors; the dynamo engine is now used as a stand-by to the line shaft engine; the electrical plant driven off the other one is transferred to Corporation mains.

St. Anne's-on-the-Sea.—Have a consumer on their mains who also has a suction gas plant, but as good revenue is obtained, the presumption is that the suction gas plant is not used exclusively.

St. Helens.—Have only met one suction gas plant in competition; the firm in question have a stand-by supply from Corporation mains, which is frequently called into requisition.

Stafford.—Have a suction gas plant and electricity, both running in one works, and are of the opinion that when the suction gas plant is worn out it will be replaced by a motor.

Walthamstow.—Have obtained the extension for electric motors 100 h.p. with a firm who are using gas plant.

Warrington.—A firm of corn merchants put down a 40 h.p. suction gas plant three years ago. This firm states that had the price of electricity been what it is now, the plant would not have been put in. Current would be about 0·96d. An iron-founder put in a 20 h.p. suction gas plant four years ago, and the owner likewise states that with current at its present price, suction gas would not have been considered. Current would be about 1d. per unit. A firm of wire drawers, who have a capable engineer and staff of fitters, put in a 30 h.p. plant on a 90 per cent. load factor; and they also state that with current at its present price gas would not have been put in; the price of current in this case would be about 0·69d. Another firm have a stand-by from Corporation mains for suction gas driven dynamo; a fair revenue is obtained from this, so presumably the gas plant is not used exclusively. A large engineering works, having staff of engineers, chemists, &c., states that it costs 0·9d. per unit without capital charges for energy for gas-driven plant of 250 h.p. There are several isolated suction plants some distance from our mains.

Watford.—Supply a firm with electricity at 1¼d. per unit on high-tension side in place of using their suction plant. A second firm would take supply of electricity in preference to using their suction gas plant, if they could get it at under 1¼d. per unit.

West Bromwich.—State that they have superseded a suction gas plant of 3-50 h.p. engines in large ironworks; the fuel costs were 0·6d. per unit, works costs (water, wages, and repairs) 1·5d. to 2d. per unit; to this have to be added capital charges.

West Ham.—Have replaced one suction gas plant by motors, and are on the point of replacing two others.

The Charing Cross, West End, and City Electric Supply Company.—Report that very few suction gas plants are in use.

Northampton Electric Light and Power Co., Ltd.—Have reason to believe they will obtain the business of a firm who discarded a suction gas plant for steam in another town.

Success in competition against suction gas is also reported from Ayr, Birkenhead, and Leith. Competition is mentioned to some extent in Southwark, Norwich, Patricroft, Rochdale, but no particulars as to the result are given. The following authorities, however, report that they have not experienced much competition:—Hammersmith, Hampstead, Bolton, Bootle, Broughton, Bristol, Carlisle, Chester, Crewe, Edinburgh, Lincoln, Liverpool, Motherwell, Newport, Nottingham, Southampton, Sunderland, Wimbledon, Worksop, York, Notting Hill, South Metropolitan Co., Bournemouth, Kent Power Co., Richmond, and Prescot. Several other engineers state that very few suction plants exist in their districts.

ELECTROMETALLURGY AND ELECTROCHEMISTRY

IN the *Chemiker Zeitung* (1908) 32 1104, F. Bölling describes a new product of the electric furnace, which he calls silundum. It is a silicide of carbon, and is obtained by heating carbon in an atmosphere of vapour of silicon. In other words, by heating carborundum with carbon, to which, if necessary, sand or a mixture of sand and carbon is added, and the temperature kept at between 1700 and 1800° C. It would thus appear that silundum is an intermediate product between carbon and carborundum. Articles of carbon may be, if so desired, converted into silundum on one side, or in particular places only. As might be expected, the electrical conductivity of silundum is considerably inferior to that of carbon. It varies, however, as also does its hardness, according to the length of heating which the carbon has undergone in the silicon vapour. It is found that a rod 8 cm. long and 0·6 cm. in diameter will dissipate 4,000 watts continuously and permanently, and even 8,000 watts for short periods. The substance is quite stable in air up to temperatures of from 1750–1800° C., when silicon vapour commences to be given off, and it is at once oxidised. It is destroyed by molten metals, particularly by iron, therefore if it is used for making crucibles, the outer part only should be converted into silundum. Attempts have been made to employ it for making filaments for incandescent lamps, but on account of the deposition of a brown film of silicon on the glass, it is useless for this purpose. It is hoped that it may be found valuable as a permanent resistance material for high temperature operations.

Ad. Jouve contributes an article of considerable interest to the *Elektrochemische Zeitschrift* of January, in which he describes the electrochemical exhibit at the International Electrical Exhibition at Marseilles in 1908. The chief interest of the article centres in the picture it gives of the great hold of the electrometallurgical industry in France. Thus the Société Electrométallurgique française showed various iron and steel alloys, such as tungsten steel, ferro-nickel (40 per cent. Ni), ferro-chrom (60 per cent. Cr.), ferro-silicon (25. 50, and 75 per cent. Si), and various varieties of cast steel which latter was characterised by its very small phosphorus and sulphur contents. Usines Electrique de la Louza et de l'Electro-chimie Niçaise, similar products, and also ferro-aluminium. Société Electrométallurgique pour les Procédés Paul Girod, the well-known Girod alloys, amongst which there was tantalum steel (34 per cent. Ta), nickel-chrom-steel. Etablissments Keller and Leleux also showed different ferro-alloys, as also did the Société de la Néométallurgique et Société electrochimique de griffe, who also exhibited 96 per cent. manganese, iron-silicon-aluminium alloys, nickel boron (75 per cent. Boron).

Compagnie des Produits chimiques d'Alais et de la Camargue aluminium, and various alloys and bronzes, also tungsten metal and tungstic acid. La Volta-Werke, electrodes of ferro-silicon (25 per cent. Si), the amount of silicon seems very low if these electrodes are to be employed as anodes. Electrodes of ferro-silicon containing 80–95 per cent. silicon, have been suggested by R. Krause (German Patent, 195,518), to be employed as anodes in zinc and copper solutions. Cie Universelle d'Acétylène, showed various forms of calcium carbide, ferro-silicon, and different forms of acetylene generating apparatus. Sté des Carbures métalliques et d'Electrochimie, apparatus of graphite, anodes for aluminium manufacture, calcium carbide, barium carbide, strontium carbide, potassium and sodium chlorate, metallic sodium, metallic calcium, ammonium perchlorate, sodium peroxide, &c. Société Française des Produits Azotés exhibited calcium cyanamide and ammonium sulphate. Electrométallurgie du Carbure de Calcium Charles Bertolus, silicon-manganese, silicon-chromium alloys, metallic chromium, and a large variety of iron alloys.

Elektrometallurgische Werke Arlod, silicon-steel, and various forms of calcium carbide. Société Norvégienne de l'Azote (Notodden in Norway), anhydrous nitric acid, calcium nitrate,

Digitized by Google

sodium nitrate. Société des cuivres de France, electrolytic copper, gold, silver, and platinum, the three latter obtained from the slimes produced in the refining of the copper.

With the exception of the products of the Notodden works, all these products are obtained in France. Of course the fact that in the Pyrenees water power is cheap is a great advantage. But at the same time manufacturers are ready to pay fairly high prices for special ferro-alloys, and therefore it seems high time that some attempts in this direction were made in this country.

It is a well-known fact that metal which has the least grease upon its surface cannot be satisfactorily plated upon electrolytically. Various methods are employed for removing the grease. One of the most satisfactory is to make the metal which is to be plated upon, the cathode for a few minutes in a bath of hot caustic alkali or sodium carbonate. The action, which is very rapid, is generally looked upon as being one of saponification. The metallic sodium is given up on the surface of the metal, and on the moment of its liberation is in a very active condition. In this state it immediately splits up the fatty oils, forming soluble soaps. If this, however, is the entire reason, then petroleum and other unsaponifiable oils should not be removed. Dr. Adolf Barth, in the January number of the *Elektrochemische Zeitschrift*, describes experiments which he has made with fatty oils, and also with petroleum oils. He finds that in both cases the bath works most successfully, and therefore comes to the conclusion that the cleansing process is mainly mechanical. The metallic sodium is given up on the surface of the metal, it at once reacts with the water, and hydrogen is evolved. The hydrogen bubble is given off from the electrode surface with almost explosive violence, and carries the fat or oil in its immediate neighbourhood away with it. Consequently, in a very short time—2–4 minutes—the whole of the grease is removed.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

MAGNETIC SEPARATORS.—A leaflet from Messrs. Cookson & Co., of Albion House, 59 New Oxford Street, describes their "Rapid" electro-magnetic separator for dry materials of the nature of grain, foundry sand, sawdust, &c. The material is sifted through an oscillating tray and then fed in a constant stream on to a revolving brass drum, within which are fixed electromagnets. Any magnetic material is carried round to the back of the machine, while the non-magnet material falls off the drum in front. A special machine for the removal of iron from destructor furnace slag after it has been crushed, is also described on a separate sheet. This process renders the slag more suitable for making mortar and concrete slabs.

ACCUMULATOR PLATES AND ACCESSORIES.—Two leaflets, giving particulars and prices of accumulator plates and accessories respectively, are to hand from Messrs. Cookson & Co., of Albion House, 59 New Oxford-street. The accessories include indiarubber corks, glass vents, and hydrometers. Accumulator plates of all sizes from small ignition to large traction plates are kept in stock.

THREE-PHASE MOTORS.—The latest lists of the series which is being issued by Mr. G. Wütrich, of the British Department of the Oerlikon Company, deal with three-phase totally enclosed squirrel-cage induction motors, in sizes ranging from ⅛ to 36 h.p. for pressures up to 500 volts 50 cycles.

METAL FILAMENT LAMPS.—A handsome showcard calling attention to the "Gral" metal filament lamp is being issued by the Armorduct Manufacturing Co. On it two female forms are seen floating across the sky, one of whom is holding a brilliant incandescent lamp.

FANS.—A handsomely produced catalogue, giving particulars of the Keith fan for pressure or extraction, is to hand from the James & Blackman Co., Ltd., of 27 Farringdon Avenue. In a frontispiece to the catalogue Father Time is shown soliloquising to the effect that *Punch* is quite right that the triumphs of 1908 were mostly in the air, as that year gave birth to the Keith fan. In the simplest forms of this fan, both the case and the wheel are formed of light sheet steel, and are electric-rivet welded. The wheel itself is exceptionally light and rigid in construction without requiring any kind of internal stays, and it may be safely run at almost any practicable speed. It takes the form of a double-conical truncated cone of different angles, composed of curved blades of conoidal formation, having their deeper or inner ends set obliquely to the wheel axis, the diameter of the wheel both inside and outside being greatest where the blades are narrowest, and the longitudinal edges of the blades lying on conical surfaces differently inclined to the axis of the fan spindle. Very high efficiencies are obtainable over a considerable range of air pressures and volumes.

ARC LAMP WINCHES.—The London Electric Firm, of George Street, Croydon, have issued a leaflet which gives particulars of a new design of self-sustaining winch without ratchets, pawls, worm or gear wheels. Although primarily designed for arc lamps, these winches are also extensively employed for raising and lowering batteries for theatre work, a purpose for which their compactness makes them specially suitable. In addition to the ordinary pattern, they are also made with the barrels divided into sections to coil up a number of suspension ropes simultaneously.

CABLES.—The new cable catalogue of Messrs. Callender's Cable & Construction Co., Ltd., is arranged in a convenient pocket form, and contains particulars of a very complete range of "Association" and "non-Association" wires, cables, and flexibles, as well as a number of special manufactures of the firm, such as twin flexibles, simplex, duplex, and triplex aerial wires and cables, flexible leather-sheathed and cord-braided trailing cables, motor-car flexibles, shot-firing wires, &c. A particularly useful feature of the list is the inclusion of a very complete cable code, which should be found of great use by clients. *Caljquitt*, for example, means that "our present discount is 2½ per cent.," while the fortunate receiver of the word *calkjaggar* will enjoy a discount of 50 per cent. Again, *callepriual* signifies "Can you send a jointer who is expert in solid system work? If so, when?" And a guarantee about thirteen lines long is contained in the word *callpoulta*.

POWER SUPPLY ON THE RAND

IT has been officially communicated in Johannesberg that the power scheme and contract recently arranged by Mr. W. A. Harper, in Johannesberg, for the supply of electric power for the electrification of the properties of the Rand Mines, Ltd., and the mines of Messrs. Wernher, Beit & Co. and Messrs. H. Eckstein & Co., of Johannesberg, have been accepted for the supply of 15 of the mines in those groups. The mines concerned, says the *Financial News*, are Glen Deep, Rose Deep, Geldenhuis Deep, Jumpers Deep, Nourse Mines, Village Main Reef, Village Deep, Ferreira Deep, Robinson Central Deep, Robinson Gold Mine, Crown Deep, Langlaagte Deep, Bantjes Consolidated Mines, City Deep, and the New Modderfontein Gold Mining Co. The requirements of the mines in question amount to 300,000,000 units per annum.

The site selected by the engineers is 14 miles from Johannesberg, and commands 50 miles of the reef. A conservation area for two years supply of water exists at the site, and wells at shallow depths are capable of yielding 2,500,000 gallons daily. A coal seam over 100 ft. thick adjoins the station site. Supplies of coal will be also drawn from Middleburg and Vereeniging, and the average cost of coal is such that it is estimated that power will be generated at a less cost than at any other power station in the world. The scheme includes the erection of a station of six 12,000 h.p. turbo alternators. The contract has been adopted by the Victoria Falls Power Co., and that company have agreed to finance the new undertaking; in fact, the new company will form part of the great proposals of the Victoria Falls Co., and the joint output of the two undertakings combined will reach almost immediately 500,000,000 units to 600,000,000 units per annum. Some mention was made of this matter at the annual meeting of the Victoria Falls Power Co. (ELECTRICAL ENGINEERING, Vol. IV., page 592).

The consulting engineers to the new undertaking are Messrs. Harper Brothers & Co., of London, and Professor Klingenberg, of Berlin, director and engineer-in-chief of the Allgemeine Electricitäts Gesellschaft; Messrs. Siemens & Halske are also said to be associated with the contractors. A new company, having a capital of £2,000,000, will shortly be registered under the title of the Rand Mines Power Supply Co.

Finsbury Technical College Old Students' Association.—The third annual dance of this Association will be held at the Caxton Hall, Westminster, on Saturday, February 13th, at 6.30 p.m. Tickets, 4s. 6d. each, including light refreshments, may be obtained from the Honorary Secretary, Mr. E. W. Moss, 20 Huddleston Road, Tufnell Park, N.

"The Central."—The current number of this publication, the magazine of the Central Technical College Old Students' Association, contains a short obituary notice of the late Professor Ayrton, but a special number, which will be devoted entirely to his life and work, is now being prepared. Three original illustrated articles, dealing with modern lift gear, the manufacture of paper, and the Scherzer rolling lift bridge, respectively, are followed by the usual notes on the last college session. The "Old Student Notes" occupy a fair number of pages, and the number is concluded with a few reviews of recent engineering publications.

Electricity in Australian Mines.—According to the *Colliery Guardian*, a Bill has been introduced into the New South Wales Parliament to amend the State Coal Mines Regulation Act. It deals simply with the use of electricity in coal mines, providing for the appointment of a general inspector to see that all persons employed in coal mines in the working of electrical appliances are competent; also to see that the electrical installations are carried on in a proper way in accordance with the rules approved by the recent Royal Commission. The Bill also provides for the issue of certificates of competency, and makes illegal the employment of persons not possessing such certificates. The Bill, which is being accepted by the State Parliament, will come into force directly it receives the vice-regal assent.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 21st, 1909

A full list of these was published in our issue of Jan. 14th. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

28,014/07. **Magnetic Separating Machines.** THE RAPID MAGNETTING MACHINE CO., LTD., H. H. THOMPSON, and A. E. DAVIES. This specification describes a form of magnetic separating machine for picking out particles of iron or steel from grain, crushed material, rubbish, &c. The rotating drum, within which is a row of fixed radial electromagnets, is, according to this invention, built up of alternate rings of magnetic and non-magnetic material. The former correspond in position with the poles of the electromagnets, which they almost touch, and are broken up into a number of segments connected by non-magnetic material. A reciprocating tray for feeding the material on to the drum is provided as usual. This arrangement renders the action more certain than when a drum entirely of non-magnetic material is used. The width of the iron rings are varied according to the nature of the material with which the machine is to deal. Three claims, four figures. In another specification, No. 28,015/07, a machine for a similar purpose, but consisting of an inclined reciprocating tray with a floor of alternate strips of magnetic and non-magnetic material is described. The magnet poles are arranged under the iron strips as in the former machine, but alternate rows of poles are of opposite sign. Non-magnetic material is shaken off the tray, while magnetic material is retained. Five claims, five figures.

28,554/07. **Method of Jointing Wires and Cables.** BRITISH INSULATED & HELSBY CABLES, LTD., and D. B. SAUNDERSON. This invention relates to methods of welding copper or aluminium wires and cables with the aid of an oxy-hydrogen flame, or "Thermit" or other similar fusing compound. The two ends of the cable, wire, or rod are pressed together when at a melting temperature so that the oxidised metal is carried to the outside, ensuring a clean, conducting union in the centre. A special form of sleeve or trough for partially surrounding the ends of the wires during welding is described in the specification, and this is provided with movable jaws which clamp the wire, and are used for the purpose of pressing the ends together. Two claims, four figures.

153/08. **Trolley Wheel for Tramcars.** J. SHEPHERD & F. B. ULLERY. A method of mounting the wheel of a trolley-pole so as to admit of a certain amount of lateral movement of the former with respect to the latter is described in this specification. The tongue or pin connecting the support for the wheel to the pole is pivoted in a tapering socket on the top of the pole, and side-springs to cushion the lateral movement are provided. Three claims, four figures.

18,221/08. **Flexible Shaft Coupling.** SIEMENS BROTHERS DYNAMO WORKS & DR. M. KLOSS. Flexible couplings are sometimes used for turbo-generator sets in order to equalise any errors in alignment. Most couplings, however, exert a thrust parallel to the shaft axis, which interferes with satisfactory running, and the present coupling is designed to overcome this objection. This coupling is similar to the Rateau pattern in that it has a number of steel pins, but in the latter type the pins are arranged parallel to the shaft, in consequence of which a force is exerted on the shaft in an axial direction. By arranging the pins radially between between two concentric flanges, however, this trouble is avoided, and in the present pattern this arrangement is adopted. The pins are passed through holes in the outer and inner flanges, and are kept in position by a ring screwed on to the outer flange. Two claims, two figures.

21,628/08, **Surface Contact Tramway System.** THE SP. (SUCHOSTAWER PATENTS) SYNDICATE, LTD., and H. M. SAYERS. In this system of electric traction, the car receives current from studs on the permanent way through a collector which is combined with a magnet system for connecting the studs to the live conductor when the car is passing over them. According to this invention, the collector is constructed in the form of a long flexible brush composed of longitudinal steel wires which have been corrugated to a definite pitch. These wires support a number of steel bristles, which are kept in position by the corrugations, and the whole is closely bound together. This brush not only collects the current from the studs, but cleans them, and also improves the magnetic circuit, thus ensuring the certain action of the switches. Such a brush will cut through ice or snow on the studs. To diminish leakage through mud or water on the permanent way, rubber shields, extending to the surface of the road, when the brush is drawn down, are fixed on the sides of the collector. Scrapers are also fixed at each end, to protect the steel brush. Five claims, three figures.

25,029/08, **Multiple Working in Wireless Telegraphy.** S. EISENSTEIN. This is a patent of addition to patent No. 20,128 of 1907, in which connections for enabling a single aerial to be used for transmitting with different wave lengths were described. The aerial was constructed in a number of branches, the first of which consisted of the aerial proper, its inductance coils, and an electrical counterweight or capacity over earth, and all the succeeding ones of oscillating circuits and counterweights, each succeeding circuit being connected to the nodal point of the preceding one. The present invention relates to a method of tuning a receiver station in which a similarly divided antenna is used. Two claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BOULT (*Woodbridge*) [Distribution] 346/08; GUILLOT [Suspension of conductors] 1,240/08; CLEIREN [Transmission of power] 2,245/08; EXLEY & LEITNER [Series-parallel lighting circuits] 4,066/08; WOLFF [Conductors for alternating current] 13,678/08; LAND- UND SEEKABELWERKE AKT.-GES. [Cables] 17,530/08.

Dynamos, Motors, and Transformers: SCHÄFFER [Motor generator] 26,762/07; SPENCE [Flywheel machines for distribution systems] 1,559/08; SOC. FRANÇAISE DES PROCÉDÉS, J. L. RONTIN [Electromechanical governors for generators] 11,068/08; SIEMENS BROS. DYNAMO WORKS & KLOSS [Propulsion of ships] 16,491/08; R. BOSCH & Co. [Fixing of brush-holders], 21,568/08; MYSCHKIN [High-pressure motor] 22,740/08; SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens-Schuckert-Werke Ges.*) [Alternating-current commutator machines] 23,963/08.

Electrometallurgy and Electrochemistry: AWALOW [Copper refining] 26,829/07; ALLGEMEINE ELEKTRICITÄTS-GES. [Charging furnaces] 4,969/08; HELBERGER [Furnaces] 13,257/08; IMBERT [Furnaces] 17,281/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Furnaces] 23,071/08.

Ignition, Electric: COLLUM [Magneto-ignition system] 1,288/08; HANL & WALDAU [Sparking-plug] 19,201/08; HALL [Case for sparking-plugs] 20,771/08; R. BOSCH & Co. [Magneto generator] 25,855/08.

Incandescent Lamps: BRITISH THOMSON-HOUSTON Co. (*Allgemeine Elektricitäts-Ges.*) [Lamps] 10,341/08; ARSEM [Manufacture of Filaments] 17,618/08.

Instruments and Meters: BEAUMONT [Prepayment meters] 1,959/08.

Switches, Fuses, and Fittings: RIDGWAY AND BRUNT [Terminal connections] 4,683/08; BRITISH THOMSON-HOUSTON Co. (*General Electric Co., U.S.A.*) [Motor controllers] 5,611/08; DAWSON [Shades and reflectors for electric lamps] 7,674/08; BRITISH THOMSON-HOUSTON Co., HASTINGS AND WISE [Motor controllers] 7,844/08.

Telephony and Telegraphy: AMALGAMATED RADIO-TELEGRAPH Co., AND MASKELYNE [Reproduction of pictures at a distance] 658/08; RUSH [Ship Telegraphs] 4,132/08; SOC. DES TELÉGRAPH MULTIPLEX (SYSTEME E. MERCADIER) [Mono-telephone relay for printing telegraph] 6,767/08; MAXSE (*Piat*) [Telegraph relays] 10,699/08.

Traction: LOHNES [Brakes] 8,809/08; MOUNTAIN & GIBSON, LTD., AND HEAD [Tramcars] 8,870/08; PHILIPSON [Side-guard for bogie tramcars] 10,106/08.

Miscellaneous: BLUT [Burglar-alarm] 505/08; CRAIG [Ozoniser] 535/08; FERGUSON [Motor-driven navigation sounding machine] 1,655/08; RAPID MAGNETTING MACHINE Co., THOMPSON, AND DAVIES [Magnetic separator] 2,203/08; LEENDERS [Fire and burglar alarm] 10,591/08; COOPER (*Boelling*) [Resistances for cooking and heating apparatus] 21,493/08 and 21,756/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

GROB [Lighting and heating of vehicles] 28,120/08; GROB [Pole-shoes for machines with compensating windings] 28,300/08; SCHÄFFER [Manufacture of metal filaments] 28,554/08; ALLGEMEINE ELEKTRICITÄTS GES. [Transformers] 92/09; PUNGA [Single-phase series motor] 133/09; ORLING, OLDENBOURG AND SPIEGELBERG [Electro-capillary device for recording electric impulses] 275/09.

Expiring Patent

The following patent expires during the current week after a life of fourteen years:—.

2,430 of Feb. 4th, 1895. **Insulation of Wires.** G. M. HARDINGHAM. (*Felten & Guilleaume Akt.-Ges.*) This patent is for a method of insulating conductors on the air-space system, which consists in enclosing the wire in a twisted tube or cover of insulating material, such as paper, having a triangular or quadrangular section. The wire touches the sides of the enclosing tube only at intervals. A special die for shaping and twisting the tube round the wire is also described in this specification.

CORRESPONDENCE

ELECTRICAL POWER COMPANIES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I notice, in your issue of the 7th inst., an article by "A Pessimistic Correspondent" on Central Station Supply, and, in taking up the matter in a preliminary manner, I purpose confining myself strictly to the commercial aspect of the question, and to endeavour to show that, in a reasonably progressive and fairly well concentrated area of operations, there is undoubtedly a good future, combined with a prospective fair return to its investors, for any Power Company whose plant and equipment have been carefully considered, and whose distribution system has been planned and laid out with due consideration of the relation of the capital expenditure sunk in mains, etc., to the definite and prospective return on same. I frankly admit that there are many—too many—supply undertakings having their being to-day where these important essentials seem, as your correspondent would infer, to have been largely neglected, and whose plants have been designed mainly for low-power station costs, forgetting that a unit at the power station is a very different matter from a unit at the consumers' meters as regards cost to the undertaking. It does not, however, follow that all these undertakings are quite in the poor position indicated by your correspondent, whose figures, as I hope to show, are not quite sound, and would seem to refer to an undertaking not carried out on the most economical lines.

To take the various figures given in detail, the cost of the undertaking, complete with generation plant, mains, and transformer equipments, is £75 per kw. of plant installed and £100 per kw. of plant in operation, a figure which any company catering largely for power supply would find, as your correspondent suggests, oppressive. These rates per kw. would appear to me to be largely imaginary, and if not so to be taken from records where the power load must be highly unremunerative, and where a considerable amount has been sunk in undeveloped lighting mains and distributors. These latter are admittedly unremunerative per £ of capital expenditure as compared with a power consumer.

As a matter of comparison, and illustrating my point, I take the liberty of mentioning an instance where a Central Station Supply makes a fairly optimistic showing. The generating plant consists of turbo-generator units of 7,000 kw. in all, one being a 1,000-kw. machine for handling the night and week-end loads. The capital expenditure in lands, buildings, mains, transformers, services, meters, etc., is about £375,000, and the running plant load factor 46 per cent. On a maximum demand of 3,000 kw. the station costs are 0.165d. Losses in distribution, say, 20 per cent. Contracts are in hand, and the capital expenditure has already been incurred, to a large extent, which will increase the maximum demand to nearly 5,000 kw. Further, the lands, power station buildings, transformers, trunk mains, and various other items are amply large enough for a considerable increase of producing capacity, and it follows, naturally, that each new unit of plant installed in the future will be represented by a lower capital cost per kw. than at present, and also lower the cost per kw. over the whole undertaking.

Let us tabulate the foregoing figures roughly, and take the station costs at 0.165d., though undoubtedly they are shaping for 0.15d., if not lower, and the load factor as 46 per cent., though this should have a decided tendency to improve with the character of the load under contract.

This is a better position to the extent of some 20 per cent. than that submitted by your correspondent, and there is no doubt but that these costs should show a very fair return to the shareholders. What is more, they are not imaginary, and should certainly improve as the scope of operations of the undertaking widens, and the diversity of the trades supplied increases.

Output say 5,000 kw. × 46 per cent. L. F. × 0·80 efficiency = 16,118,400 units sold per annum.
5 per cent. depreciation on £375,000 = £18,750 = 0·27d. p.u. sold.

Generation costs including station and plant maintenance	0·165		
Add 20 per cent.	0·033		
		0·198	,,
Administration, mains maintenance, and standing charges... ...		0·10	,,
		0·568d.	,,

Further, 8,000kw. of plant and an output of 20,000,000 units per annum cannot be considered as near finality for a Power Company operating in an industrial area. This is mere scratching of the ground, and, under sound and progressive management, the output should, in a few years, be many times this amount, thus further reducing the cost per unit sold.

I am,

Yours, etc.,

FAIRMINDED.

THE ECLIPSE BOILER FURNACE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—We notice appearing in the Press a prospectus asking for capital for the Eclipse Boiler Furnace. Absolutely no evidence of the methods by which the claims made are to be substantiated is given except a short paragraph, which states that "the smoke is taken through a zone of high temperature due to a sort of gas blow-pipe, which burns it completely." The whole thing seems to demand further light thrown upon it, as, from the information before one, it would appear that there had been at least a thousand patents taken out in this direction, many of them fairly successful under ideal conditions, but the number of failures have been so great that they have been swept out of the market.

When capital of £100,000 is asked, it behoves those who publish such a prospectus to give full information as to the nature of the apparatus, and full particulars as to the trials alleged to have taken place. It would have been more satisfactory to Lancashire and Yorkshire readers—many of whom are at the present moment burning small bituminous coals in Lancashire boilers without smoke—to have had the opinion of some practical engineer well known as specialising largely on combustion and firing apparatus, such as Mr. Michael Longridge, of the British Engine, Boiler & Electrical Insurance Co., Ltd.

A specially wild statement is that contained in the following paragraph of the prospectus:—"Until the invention of the Eclipse Furnace, no method was known to engineers by which the highly volatile gases resulting from the combustion of coal could be consumed within the boiler, and consequently these gases are discharged into the atmosphere." Now, sir, there are plenty of mechanical stokers and furnaces actually doing this work at the present moment in hundreds of factories and works all over Great Britain, including London and Birmingham, and, to mention only a few of the makes of machines known to us as effecting smokeless combustion with bituminous slack of low grade in Lancashire boilers with economical results, we may mention the Bennis stoker, Erith Underfeed stoker, Hodgkinson stoker, Proctor stoker, Underfeed stoker, and the Vicars stoker.

If the question arises of burning bituminous fuel smokelessly under water-tube boilers, we may mention the following machines as specially adapted for the purpose:—The Babcock & Wilcox chain grate, the Bennis chain grate, the Bennis coker, the Hodgkinson coker, the Vicars coker, the Underfeed, and the Erith Underfeed.

Now all of these machines can burn—and are constantly burning—bituminous low-grade slacks smokelessly, and show considerable saving over expensive Welsh coal, and this appears to be no more than the Eclipse boiler furnace claims without convincing substantiation. We have no doubt that there would be found to be, at a very low computation, at least 20,000 of these furnaces at work. Should you wish, sir, to see smokeless combustion, we shall be very pleased to direct you to as many chimneys with hard-pressed boilers underneath them as will satisfy you as to the accuracy of this statement.

A. W. BENNIS.

Municipal and County Club, London, S.W.,
January 19th, 1909.

LOCAL NOTES

ACCRINGTON: *Proposed Light Railway.*—Local gentlemen interested in the scheme for a light railway between Huncoat and Clayton-le-Moors met at Clayton-le-Moors on January 21st. Mr. Wood, the engineer, explained that the railway would be something over two miles in length. The estimate for construction was under £24,000. Preliminary expenses would amount to between £240 and £300. The amount already promised and actually subscribed amounted to £150. A committee of three local promoters and other representative gentlemen were appointed to raise locally the whole of the preliminary expenses.

ACTON: *Electricity Staff.*—The Electricity Committee have been instructed to consider and report what changes (if any) in the staff of the electricity department are necessary.

AMBLE: *Electric Lighting.*—Councillor Wanless lectured the ratepayers last week on the advantages of electricity for public and private lighting and other purposes, and outlined a scheme of electric supply for the district.

BECKENHAM: *Arc Lamp Suspension Gear.*—The Council recently applied for sanction to a small loan for arc lamp suspension gear; but the Local Government Board have replied that they do not sanction loans for less than £100.

BRIGHTON: *Supply for Electrobuses.*—Arrangements are being made by the Corporation Electricity Department for giving a supply of electrical energy to the new garage of the Brighton and Hove Omnibus Co., who intend to place twelve vehicles on the streets. Some reference to this matter was made in the discussion at the Society of Road Traction Engineers on January 18th (ELECTRICAL ENGINEERING, January 21st, p. 70).

CARDIFF: *L.G.B. and New Loan.*—In connection with the recent Local Government Board inquiry, concerning a loan for extension of the electricity undertaking, the Inspector asked for further information in relation to certain items of the capital account, and these are being furnished by the City Treasurer. The Chairman of the Finance Committee has now suggested that the lighting and tramways committee should give effect to the following resolutions in order to put the finances of the undertaking upon a sound basis :—(1) That provision be made in the rate estimates for the ensuing year for all items which, in the opinion of the Local Government Board, should have been charged to revenue instead of to capital in the past. (2) That the revenue accounts for this department should be charged each year with a sufficient amount for depreciation based upon the principles embodied by the city treasurer in his reports to the electrical committee on December 13th, 1907. (3) That the depreciation fund, when thus established, shall be annually maintained, set aside, and invested, and exclusively kept for this purpose. (4) That, in the event of profits being available in subsequent years, any such profits might be transferred to the relief of rates, in part or in whole payment of rates in aid. (5) That the revenue deficiency (if any) at March 31st, 1909, be included in the supplementary estimates and raised in the rates to be levied for the half-year ending March 31st, 1910. Discussion of the matter has been adjourned until the next meeting of the Corporation.

DUNFERMLINE: *Tramway Extension.*—In reply to a complaint by the Council at the delay in constructing the lines for which powers were granted to the Dunfermline and District Tramways Co. in 1906, Mr. George Balfour, the chairman of the company, states that he has just acquired a controlling interest in the concern. The Order of 1906, he points out, provides that the tramways shall be completed within five years from the commencement of the Order—that is, from the date of the passing of the Confirming Act which received Royal Assent on December 21st, 1906. Although a period of nearly nearly three years has yet to elapse before the powers granted to the company shall cease, he is about to make the necessary financial arrangements, and sees no reason why the tramways should not be in operation before the close of this year, provided the usual facilities are given for making rapid progress during construction.

FELIXSTOWE: *Purchase of Electricity Works.*—The agreement between the Council and the Suffolk Electricity Supply Co., for the purchase of the company's electricity works, has been sealed.

FINCHLEY: *Street Lighting.*—In connection with the application to the Local Government Board for sanction of a loan of £2,000 for street lighting, the North Middlesex Gas Company, as one of the largest ratepayers, have asked for the assurance that no part of the contemplated expenditure will be incurred, and no work commenced, until after the Local Government inquiry, at which they intend to appear.

GLASGOW: *Kirkintilloch Tramway Extensions.*—The Kirkintilloch Town Council, on the motion of the local Merchants' Association, has decided to ask the Glasgow Corporation not to proceed further with the proposed tramway extension to Kirkintilloch. The reason given is that in other outlying districts to which the Glasgow tramways have been extended, local trade had been practically ruined.

HERNE BAY: *Electric Lighting.*—Messrs. Lacey, Sillar & Leigh have prepared a report upon an electrical installation for the district.

HIGHGATE: *Tramcar Accident.*—A driver in the service of the Metropolitan Electric Tramways, Ltd., has been charged with the manslaughter of a child, aged twelve, who was run over and killed by a tramcar in Archway Road. It appears that something went wrong with the controller at the driving end of the car, and finding he could not put it right, the driver attempted to run the car from the conductor's end, *i.e.*, backward, in order to report to the officer at Highgate Archway. The boy was sitting on a ladder at the rear of a brewer's dray when the car ran into the latter and crushed the boy. The car was proceeding uphill at the time, and culpable negligence is alleged from the manner in which the car was being driven. At the inquest the jury returned a verdict of "Accidental Death," adding that to drive the car from the rear was an error of judgment on the part of the driver and conductor.

HUDDERSFIELD: *Tramway Finance.*—For the nine months ended December 31st, the revenue of the tramways department was £64,652, compared with £65,006 for the corresponding period of the previous year; the working expenditure for the two periods being £34,688 and £32,054 respectively. After payment of £904 for rent of the Linthwaite lines, £9,914 interest on capital, £7,440 for redemption of debt, and setting aside 3 per cent., or £9,290, for depreciation, there was a net surplus of £2,416, against £5,306 in the last nine months of 1907. The reserve or renewals account now amounts to £32,368. The total capital expenditure amounts to £412,903.

ILFORD: *Tramways Management.*—At a meeting of the Ratepayers' Association last week, a resolution was passing urging the Council to appoint a tramways manager. At present the management is in the hands of Mr. A. H. Shaw, the electrical engineer, and although no complaint is made against him, the feeling seems to be that the loss upon the tramway system is due to the fact that his duties as electrical engineer do not permit of him giving sufficient time to tramway matters.

LIVERPOOL: *Tramway Traffic.*—During the year 1908 the receipts from the tramway undertaking were £562,028, as against £571,929 in the previous year. The passengers carried numbered 121,927,383, compared with 124,042,739 during 1907. The report on the first-class cars to Aigburth recommends that the experiment should be continued for a further period of six months. Although the receipts have decreased, the earnings have been maintained at the satisfactory figure of 11·02d. per car-mile. It was pointed out at the last meeting of the Corporation that during January, the receipts had increased by nearly £600 per week, which was regarded as a sign that the period of bad trade was passing away.

The Trackless Trolley System.—The Tramways Committee have decided to accept the vote of the ratepayers against seeking powers to adopt the trackless trolley system, and thus to avoid the expense of taking a poll.

The Rule of the Road.—In reference to the recent decision of the Courts that in passing a tramcar, an overtaking vehicle must not pass on the left-hand side, but, as in the case of all other traffic, on the outside, the Corporation have instructed the Town Clerk to communicate with the Local Government Board with a view to securing an amendment of the law in this respect. The Tramways Committee consider that by the recent interpretation of this rule, viz., that a tramcar comes within the meaning of the term "carriage," the safe conduct of the tramways is jeopardised, as in the case of a street with a quick service of cars, a motor car, for instance, would have to be continually threading its way in and out of them.

LONDON: *London County Council: Tramways.*—Col. Yorke on Thursday inspected the new line from Lavender Hill through Queen's Road to Chelsea Bridge. Having traversed the route in a car, Colonel Yorke expressed the opinion that it was the best piece of track he had ever travelled on. The line was constructed by the L.C.C. works department at a cost of £28,000. As a through service will be maintained to Highbury in the north *via* Nine Elms Lane, in addition to a service to Chelsea Bridge, the cars are of the single-deck type.

The new tramways running over Putney Bridge, referred to on page 73 of our last issue, were put into operation on Saturday. Over the bridge the lines are laid on either side of the roadway, within three feet of the pavement.

It is announced that the total traffic receipts upon the Council's tramway system, from April 1st, 1908, to January 16th, 1909, were £1,237,294 for lines worked by electric traction, and £226,103 for lines worked by horse traction, or a total of £1,463,397. The receipts in the corresponding period in 1907–8 under the same heads were £981,817, £318,384, and £1,300,201 respectively.

Dispute re Paving Materials.—The Highways Committee recommend that application be made to the Board of Trade, under the provisions of the London County Council Tramways (Electrical Power) Act, 1900, to appoint an arbitrator to determine the questions which have arisen between the Council and the Bethnal Green and Hackney Borough Councils with regard to the paving materials to be used in connection with the reconstruction of the tramways from Hackney Road *via* Mare Street

Digitized by Google

and Lower and Upper Clapton Roads to Stamford Hill. The Councils in question require wood paving, but owing to the extra cost of this and less durability compared with granite sets, the County Councils refuses to acquiesce unless the Borough Council co-operate in some way to bear a portion of the extra expenditure entailed.

Car-shed Arbitration.—In May last year the Council decided to go to arbitration on certain points in dispute with regard to the contract with Messrs. Holliday & Greenwood for the erection of the Stamford Hill tramways car-shed. The arbitrator, Mr. William Flockhart, F.R.I.B.A. has now issued his award, by which the Council is required to pay £1,532 10s. 3d. to the contractors and half the arbitrator's fee of £150. The total sum payable by the Council is therefore £1,607 10s. 3d., as against the contractors' claim of £6,061 17s. 8d.

Through Bookings.—The Highways Committee recommend that arrangements for through booking should be made with the West Ham Corporation in respect of the Council's lines from Aldgate to Bow, and the West Ham tramways from Bow to Stratford. A schedule of fares has been agreed between the two authorities.

Hammersmith: Shepherd's Bush Exhibition.—The Electricity Committee have been in negotiation with the owners of the exhibition grounds and buildings at Shepherd's Bush for a supply of current to future exhibitions. The company are prepared to enter into an agreement to take current for lighting and power purposes for five years from January 1st, 1909, but in the event of the Council's supply being insufficient the company are to have the right to instal plant to supplement the Council's supply. The Electrical Engineer is of opinion that by a capital expenditure of £575 for transformers, &c., the Council can supply a maximum demand of 1,700 kilowatts. This supply, however, could be increased to 2,200 by laying an additional main, but this work would increase the estimated cost to £2,025. The Council has agreed to supply electricity to a maximum demand not to exceed 2,200 kilowatts, and the Committee are to arrange for the provision of the transformers, and, if necessary, of the additional main.

Poplar Tramways.—The Borough Council has made a suggestion that the County Council should construct tramways round the Isle of Dogs. The proposal is receiving attention at Spring Gardens.

Shoreditch: Electrical Exhibition.—An electrical exhibition is to be held in October next.

Southwark: Electric Supply.—For the purpose of endeavouring to arrive at an arrangement with the London Electric Supply Co. concerning the present and future position of the municipal electrical undertaking in Southwark, the Council has appointed a sub-committee to meet the company's representative at a conference on the subject.

Westminster: London Electric Power Supply.—The Law and Parliamentary Committee in a report object to the repeated attempts made by the London County Council to obtain provisions in private Bills which encroach upon the jurisdiction of the City Council. These attempts, both by the late and the present County Council, had involved the City Council in considerable expense, and special mention is made of the London Electric Supply Bill and the London (Westminster and Kensington) Electric Supply Bill, 1908. A recommendation by the committee to send a protest to the County Council against the continuance of this policy has been confirmed.

Subways.—At the meeting of the City Council on Thursday, it was decided to lodge a petition against the Baker Street and Waterloo Railway Bill, which seeks to relieve the company of the obligation to construct subways in Trafalgar Square to the south side of Charing Cross, opposite the Phœnix Fire Office. An agreement was made between the City Council and the company for the construction of such subways, as a result of which a previous Bill was unopposed.

LYME REGIS: *Electric Supply.*—The local Press is greatly agitated on account of the Council having decided to oppose the proposal of establishing a Lyme Regis Electric Light and Power Co., in committee.

MADRAS: *Electric Supply.*—Considerable progress is being made with the works of the Madras Electric Supply Corporation. A site of some 15 acres has been secured, and in the centre of this a large building is being erected, in which the machinery which will generate the electric power is being put up. The building now in course of erection is one of the largest of its kind in India, if not the largest, and it will contain machinery capable of developing about 5,000 h.p. The boilers have been erected, and the work of fitting up and fixing the pumps, water storage tanks, and the necessary pipes is being rapidly proceeded with. The switchboard is nearly complete, and all the distributing mains have been led into the building and connected up.

MANCHESTER: *Trackless Trolley System.*—The Tramways Committee have intimated that they will accept the adverse vote of the ratepayers upon the clauses in the Corporation Bill relating to the use of the trackless trolley system, and delete them from the Bill.

MIDDLESEX: *Tramways.*—The Board of Trade has extended the time for the construction of the County Council tramways from Acton to Willesden until December 31st, 1909. The trackwork has already been completed.

The construction of the line from Cricklewood to Finchley, which will link up Willesden with Highgate and the north of London, has been commenced. This is the last line for which the County Council have powers.

OLDHAM: *Supply of Fittings, &c.*—The local electrical contractors have strongly protested against the clause in the Corporation's Bill, which gives powers to undertake the wiring and fitting of premises, &c., but so far the Electricity Committee is not disposed either to omit or modify it.

OSSETT: *Mains Laying.*—A complaint is to be lodged with the Board of Trade as to the unsatisfactory manner in which the Yorkshire Electric Power Co. have laid their mains in the borough. The Council has decided that in future the trench digging and reinstating shall be carried out by the borough engineer's department, and the cost charged to the company.

OXFORD: *The Tramway Question.*—Sir Alexander Kennedy has been retained by the Corporation to advise them on the tramway question.

RHYL: *Light Railway Proposal.*—The Light Railway Commissioners will hold their inquiry into the extension of the Llandudno tramways to Rhyl on February 20th instead of January 30th. The Council will oppose the Order.

RIO DE JANEIRO: *Telephony.*—The Brazilian Electricity Co. of Berlin—or, rather, the Electricity Co. for Brazil—which controls a subsidiary concern at Rio de Janiero for the working of the telephone system in that city, reports, says the *Financial News*, on that account a loss of 2,460 marks for the business year 1907–8, as against a profit of 1,566 marks in the preceding year. This shortcoming will be covered by withdrawals from the reserve fund. It may be mentioned that in the last balance-sheet of the Electricity Co. for Brazil the telephone plant at Rio de Janeiro was valued at 5,518,302 marks, as against 3,665,002 marks in the previous year.

SOUTHPORT: *Sale of Electric Fittings.*—In deference to the wishes of the local electrical contractors, the Corporation has decided to discontinue selling fittings at the show-room of the Electricity Department.

SOUTH SHIELDS: *The North and South Shields Electric Railway.*—A scheme has been placed before the Council by Mr. E. Schenk, on behalf of the promoters of the North and South Shields Electric Railway. It is proposed to form a company with a capital of £100,000, which will be issued as 4 per cent. debenture stock, the interest upon which the North and South Shields Corporations are asked to guarantee, to the extent of making good the deficit between the net revenue of the company and the sum necessary for meeting the debenture interest. The debenture stock would be a first charge on the undertaking, and the company would have no powers to increase the total amount of debentures without the consent of the two corporations. The first directors of the company are not to exceed five, of which three are to be approved by the Corporation. Mr. Schenk puts this forward as the only practicable method of giving the quicker and more convenient access between North and South Shields, which has been needed for so many years. Failing the co-operation of the municipalities concerned, he says the project must be abandoned. As we have already reported, an extension of time for the completion of the works is being sought in the coming session of Parliament.

SWANSEA: *Street Lighting.*—A Joint Sub-Committee of the Electric Lighting and Streets Committee had recommended that all the streets traversed by the tramways should be lighted by electricity. Consideration of the matter has been postponed, however, until the surveyor has submitted a report as to the number, type, and cost of the arc lamps required.

TORQUAY: *The Tramway System.*—A petition has been deposited by the Corporation against the tramway company's Bill, which seeks powers to extend the tramways to Paignton.

WINNIPEG: *Purchase of Tramway Systems.*—It is stated that the negotiations pending between the Municipality of Winnipeg and the Winnipeg Electric Street Railway Company for the acquisition of the company's entire plant, roughly valued at £3,200,000, have culminated in an offer by the company to sell their undertaking by arbitration as a going concern.

YORK: *Excess Expenditure.*—The Local Government Board have intimated that if the Council will make sufficient provision in the estimates for the general district rate during the next two years for paying off the debit balance of £4,927 on the revenue account of the electricity undertaking and deductions of £1,861, representing items of expenditure properly chargeable to the revenue account of the electricity undertaking, and the debit balance of £2,837 owing on the destructor account, they are prepared to give the Corporation sanction for the following sums, to be repaid in varying periods:—£17,290, being excess expenditure on electric light undertakings, and £5,253, representing the amount of the principal on the electric light department expenditure which should have been repaid in respect of the excess expenditure had the loans been raised at the time the expenditure was incurred. They are also prepared to give running sanction for £2,400 prospective expenditure on electric mains, £900 on house services, £500 on meters, and £800 on motors. The Town Clerk has been instructed to give the undertaking required.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

BARKING.—Tenders are to be invited for the supply of 4,000 tons of Welsh or 5,000 tons of bituminous coal for either one or two years.

BELFAST.—Messrs. Preece & Cardew have recently reported upon the supply of electrical energy for the Harbour Estate, and recommend a scheme, entailing an expenditure of £12,000, by installing additional machinery in the existing power house. Before coming to a decision, however, an interview is to be had with the Belfast Corporation to see if a supply can be had from the Corporation power station.

COLONIAL.—The Glasgow Chamber of Commerce has particulars of an electrical contract for the Colonies for which British firms only are requested to tender. Applications should be made to the Glasgow Chamber of Commerce at once.

LLANDUDNO.—A Lancashire boiler is required at the electricity works.

MANCHESTER.—The Corporation Waterworks Committee invite tenders for a battery, reversible booster, switchboard, &c., at their Longdale works. (See an advertisement this week.)

PENGE.—A Committee has been appointed to formulate a scheme of electric supply for the district.

Miscellaneous

BLACKBURN.—Tenders are invited for stores for the Electricity and Tramway Departments (see an advertisement this week).

LONDON: *Bermondsey.*—Tenders are invited for the supply of stores for the electricity department during the year ending April 1st, 1909, including the following:—Arc lamp carbon and brushes, cable and jointing materials, conduits, electricity meters, demand indicators, and main fuses, engine oils, meter boards, street frames and covers, and joint boxes. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk, by February 15th.

Marylebone.—Tenders are invited for stores for the electricity department, including house cables and flexible cords, dynamo and carbon brushes, installation accessories and lamps (carbon and metal filament), arc lamp carbons and globes, &c. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 16th.

Poplar.—Electric fittings are to be supplied at a cost of £352 for a fitter's shop, a blacksmith's shop, &c., which are to be erected at the central generating station. The £352 includes an item of £115 for wiring, provision of motor, &c.

ST. HELENS.—The tramway lines between Portico and Prescot are to be relaid at an estimated cost of £6,200.

SOUTHEND.—Track reconstruction is to be carried out at an estimated cost of £490, and additional loops are to be built at an estimated cost of £968.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

N.—Receiving ward accommodation at St. John's Road Workhouse, Islington. Builders, McLoughlin & Harvey, Ltd., 13 Brecknock Road, N.W.

N.—Receiving ward accommodation at St. John's Road Workhouse, Islington. Builders, McLoughlin & Harvey, Ltd., 13 Brecknock Road, N.W.

S.E.—Additions to Torridon Road School, Lewisham. Builders, Griggs & Sons, 71 Manchester Road, E.

Hall, Besson Street, Deptford. Architect, J. H. Waterworth, 385 Queen's Road, S.E.

Schools, Griffin Road, Plumstead, for the Rev. Staunton, Anglesea Avenue, Woolwich.

S.E.—Additions to Torridon Road School, Lewisham. Builders, Griggs & Sons, 71 Manchester Road, E.

Hall, Besson Street, Deptford. Architect, J. H. Waterworth, 385 Queen's Road, S.E.

Schools, Griffon Road, Plumstead, for the Rev. Staunton, Anglesea Avenue, Woolwich.

S.W.—Church, Culmstock Road, Clapham Common. Architect, J. S. Quilter, 71 Christchurch Street, Brixton, S.W.

Mortuary and coroner's court, adjoining Earlsfield Station, Wandsworth. Architect, Borough Surveyor, Wandsworth.

W.—Special school, Brook Green (£3,285), Hammersmith. Builder, E. Triggs, The Chase, Clapham.

Building on site of 174, 175, and 176 Piccadilly, and 52 and 53 Jermyn Street. Architect, G. T. Gill, 70 Carlton House, Regent Street.

PROVINCES.

ABERGAVENNY.—Extensions at Town Hall, £2,500. Architect, Mr. E. A. Johnson, St. Mark's Chambers, Monk Street.

ALTRINCHAM.—New hospital (£8,700). H. E. Brown, Surveyor to Urban District Council.

BLACKPOOL.—Hydropathic establishment. Architect, W. A. Thomas, 14 Dale Street, Liverpool.

BRIDLINGTON.—Schools and caretakers' residence (£8,600). Architect, J. Earnshaw, Carlton House, Bridlington.

Enlargement of High School for Girls (£6,650). Architect, J. Bilson, Parliament Street, Hull.

CANTERBURY.—Proposals are under consideration for the electric lighting of both the Canterbury and Herne Bay workhouses. The Canterbury workhouse is at present lighted with gas at a cost of £220 per annum, and the estimated cost of electric lighting with metal filament lamps is put at £93 per annum.

CHESTER.—Municipal buildings. Architect, T. Lockwood, Foregate Street, Chester.

COVENTRY.—School, Windmill Lane. J. Willmott, County Surveyor, Warwick.

DUDLEY (WORCESTERSHIRE).—School. Architect, T. Grazebrook, 23 Wolverhampton Street, Dudley.

EPSOM.—Workshops for the Governors of Epsom College.

ERDINGTON.—School. J. Willmott, County Surveyor, Warwick.

GARSTON (LIVERPOOL).—Schools. Architect, E. Ware, Exchange Street, East Liverpool.

GLASGOW.—School, Hyde Park. Architect, Dykes & Dell, 65 West Regent Street.

HASTINGS.—Enlargement of Town Hall. B. F. Meadows, Town Clerk.

LIVERPOOL.—Dental hospital. Architect, G. C. Fraser, 14 Dale Street, Liverpool.

Schools, Gladys Street, Liverpool. Architect, W. Sprouts, 18 Cook Street, Liverpool.

Cold storage warehouses. Deacon & Horsburgh, 81 George Square, Liverpool.

School. Architects, Bradbury & Son, Cork Street. Builders, W. Hall & Son, Liverpool.

MANSFIELD.—Police station. County Surveyor, Shire Hall, Nottingham.

NEWCASTLE-ON-TYNE.—Additions to Rutherford College, £6,000. Surveyor, F. H. Holford, Town Hall.

NOTTINGHAM.—Wesleyan Institute. Architect, A. E. Lambert, 22 Park Row, Nottingham.

PORTSMOUTH.—Police-station at Eastney (£1,470). Surveyor, P. Murch, Town Hall.

ROCHDALE.—Baths at Castleton (£8,285). Surveyor, S. S. Platt, Town Hall.

SMETHWICK.—Technical school (£15,500). Surveyor, C. J. Fox-Allin, Town Hall.

SOUTH SHIELDS.—Additions to baths and washhouses. Architect, J. Morton, King Street, South Shields.

SUTTON.—Police-station. Architect, E. P. Hooley, Shire Hall, Nottingham.

WIGAN (LANCS.).—Theatre. J. Thomley, Wigan, Lancs.

TENDERS RECEIVED AND ACCEPTED

BECKENHAM.—The following tenders have been accepted for the electricity undertaking:—British Thomson-Houston Co., Ltd., meters, £153 11s.; Lucy & Co., Oxford, lead boxes, 6s. 8d.; triple lead boxes, 7s.; cut-outs, 6s. 4d.; triple cut-outs, 11s. 6d.

BRADFORD.—The tender of the British Thomson-Houston Co. for two 3,000 kw. turbo-alternators, with Worthington condensers, is recommended for acceptance.

DUBLIN.—Messrs. Ed. Bennis & Co., Ltd., of Little Hulton, Bolton, have received, per Messrs. Babcock & Wilcox, Ltd., a contract for one "Bennis & Miller-Bennett" chain grate stoker for a Yarrow boiler, for the Pigeon House Fort Electricity Works.

LONDON: *London County Council.*—The tender of Messrs. T. W. Ward, Ltd., for the purchase of old rails at £2 10s. 3d. per ton. The following tenders have been obtained from selected firms, for the supply of wiring material required for use at the Camden Town electricity sub-station:—Edison and Swan United Electric Light Co., £64 6s. 5d. (less 2½ per cent.); Pinching & Walton (recommended), £63 10s. 3d.; Veritys, Ltd., £68 3s. 5d. (less 2½ per cent.); General Electric Co., Ltd., £66 12s. 5d.; Johnson & Phillips, Ltd., £74 1s. 3d.; Spagnoletti Ltd., £78 10s. 10d. (less 2½ per cent.).

Tenders have been received from Messrs. Tangye's, Ltd. (£782), and Messrs. J. Holroyd & Co. (£1,122) for certain electrical shop machinery at the tramways central car repair depot, and the former has been accepted.

Digitized by Google

The following tenders have been received from selected firms, for the supply of five steam-heated impregnating cylinders required for use at the tramways central car-repair depot:—Heenan & Froude, £152; Mountain & Gibson, £162 10s.; A. Goodwin & Son, £183 15s.; East Ferry Road Engineering Works Co., Ltd., £232 10s.; Thames Ironworks, Shipbuilding and Engineering Co., Ltd., £275. The lowest tender received, viz., that of Messrs. Heenan & Froude, has been accepted.

The tender of Messrs. Heenan & Froude, at £56, for the supply of a water cooler and accessories required in connection with the air compressor at the tramways central car-repair depot, has been acepted.

Poplar.—The tender of Nicholds & Reynolds at £297 has been accepted for the erection of reinforced concrete buildings (workshops, mess-room, lavatory and store-room), at the generating station.

MAIDSTONE.—An order for a 500-volt battery and "Entz" booster for the tramways has been placed with the Chloride Electrical Storage Co., Ltd.

COMPANIES' MEETINGS AND REPORTS

EAST LONDON RAILWAY CO.—The report for the year ended December 31st states that the proposed electrification of the line has had the continuous attention of the lessees and their managers. At the last meeting of the Joint Committee, when the subject was again considered, it was decided, largely on account of the heavy capital expenditure, increased running expenses, and enhanced maintenance charges, that the equipment of the railway for electrical working could not be undertaken at present. This decision was founded on the experience of other companies by whom statistical information was furnished. Whilst the directors greatly regret this, they are inclined to the belief that it is the best course to take, in view of the uncertainty existing as to which is the best system of electric traction to adopt. The completion of the electrification of the section of the London, Brighton & South Coast Railway will, they state, no doubt prove of considerable assistance in coming to a decision on the subject.

The Chairman, Lord Claud Hamilton, in referring to the matter of electrification at the meeting on Monday, said that the chief unsatisfactory feature was the continued decrease in passenger receipts, mainly due to the discontinuance of through-working over the line, arising from its not being worked electrically. Some allowance must also be made for the competition of electric trams and motor-omnibuses, but non-electrification was the main factor. This matter had been considered, but the general managers advised the committee that they could not at present recommend electrification. It was disappointing, because it meant delay for an indefinite period, but he trusted that, if the experience of the Brighton Co. with regard to the experiment on its South London section were satisfactory, matters might assume another shape. Unfortunately, they had no reason at present to think that it was certain to be satisfactory, because the contract had taken much longer to complete than was anticipated, and it was rumoured that the estimates had been greatly exceeded. It remained to be seen whether that line could be worked cheaper than the third-rail or low-tension direct-current system. In this country, although electric working of railways was much appreciated by the public, its extension was very tardy. There must be some good reason, and he suspected it was that electrical working on the low-tension direct-current system, as compared with steam, had proved too costly. It remained to be seen whether the single-phase system would prove more economical. The action of the lessee companies in hesitating to proceed at present with the electrification of the line could, therefore, be understood.

BLACKPOOL AND FLEETWOOD TRAMROAD CO.—A dividend of nine per cent. per annum is recommended for the half-year to December 31st. It is also recommended that £1,500 be placed to depreciation reserve, and £500 to the general reserve, carrying forward to the current half-year the balance of £2,054.

DIRECT UNITED STATES CABLE CO.—At the annual meeting on Tuesday the report and accounts given in our last issue were adopted. Mr. E. M. Underdown, K.C., who presided, said that he knew nothing whatever of the rumours as to a projected Government cable to Canada.

CITY & SOUTH LONDON RAILWAY CO.—At the meeting on Tuesday the report and accounts given last week were adopted. Mr. C. B. Stuart Wortley, the chairman, expressed regret that the gross receipts showed a decrease of £2,452, and that the amount available for distribution had decreased by £1,728, as compared with the corresponding period of last year. With regard to the recommendations of the officers of the Board of Trade, arising out of the fire in July, he said that the protective works now being carried out by the company went further than the Board of Trade requirements. The Bill deposited by the Central London Railway Co. for an extension of their line to Liverpool, involved the construction of a high-level subway at the Bank station, and the City & South London Company's share of the cost was estimated at £3,500.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £63 to 63 10s. per ton (last week, £64 5s. to £64 15s. per ton).

E.C.C. STAFF DINNER.—The second edition of what may be termed the new series of E.C.C. staff dinners was held at the Star and Garter Hotel, Wolverhampton, on Saturday, January 16th, Mr. William Bulloch (manager) presiding. The great increase in attendance over last year (74 as against 40) is an indication of the forty's enjoyment of the first event, and of their missionary work in the interval. No one was disappointed; the dinner was excellent and well served, while the smoking concert proved once again that the Electric Construction Co. possesses men of more than electrical parts. The opportunity was taken of presenting a case of pipes to the ever-willing and patient accompanist, and of introducing an original song, in which the staff sang its own loyalty and the high praises of its popular chief.

FIRE.—Messrs. Pritchetts & Gold inform us that a fire occurred at their works at Feltham in the early hours of the 21st inst. Considerable damage has been done, but steps are being taken to restore matters to a normal condition as soon as possible, but some inconvenience and slight delay in deliveries will be unavoidable.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The Mexican Power Development Syndicate, Ltd., is to be voluntarily wound up. Mr. A. W. Tait, Basildon House, Moorgate Street, London, is liquidator. A meeting of creditors will be held at the above address on February 1st, and particulars of claims should be forwarded at once.

The public examination of Mr. T. Ward, managing director of Electrical Instruments Manufacturers, Ltd., has been fixed for 10 a.m. on Friday, February 5th, at the Court House, Edmonton.

The liquidator in the winding-up of the Sir Hiram Maxim Electrical & Engineering Co., Ltd., has been released.

An application for discharge by C. H. Vere, electrical engineer, 5 Park Parade, North Finchley, will be heard on February 23rd at 12.30 p.m. at the Barnet Town Hall.

MANCHESTER ELECTRICAL EXHIBITION.—Creditors of the Manchester Electrical Exhibition are requested to send particulars of their claims to W. Davenport, 2 Queen Anne's Gate, Westminster, London, S.W. (see an advertisement this week).

PLANT FOR SALE.—The Bury Corporation have for sale two generating sets (see an advertisement this week).

MESSRS. MORRIS-HAWKINS.—We are asked to notify that Messrs. John Roberts & Co., of Cleveland Buildings, Market Street, Manchester, will cease to be the representatives of Messrs. Morris-Hawkins, Ltd., for Lancashire after January 31st, and all communications after that date should be addressed to the company at 75b Queen Victoria Street, London, E.C.

APPOINTMENTS AND PERSONAL NOTES

The will of the late Mr. R. B. Sperling, a director of the British Columbia Electric Railway Co., Ltd., has been proved at £23,771.

A recommendation by the Electric Lighting Committee of the Edinburgh Corporation that the salary of the station superintendent at the McDonald Road power station should be increased from £270 per annum to £300, and subsequently by two annual increments of £15, was negatived by the Corporation last week.

The applications for the post of electrical engineer to the Swansea Harbour Trust at £250 per annum having been reduced to three, these gentlemen were asked to appear before the Executive Trust on Thursday. Two failed to appear, however, and the candidate who did turn up declined the appointment.

Mr. C. E. L. Stewart, chief assistant electrical engineer at Rochdale, has been appointed borough electrical engineer at Rawtenstall at a salary of £200 per annum.

Telegraph Traffic.—On the 19th inst. the cable between Tourane and Amoy ceased working, and on the 23rd inst. communication between Hotaradja and Sabang was subject to delay owing to defective working, telegrams being sent daily by boat from Sabang. Communication between Rome and Constantinople was restored to working order on the 23rd instant.

Light Railway Orders.—The Board of Trade have recently confirmed the undermentioned Orders, made by the Light Railway Commissioners:—(1) Bath Electric Tramways (Light Railway Amendment) Order, 1909, amending the Bath & District Light Railway Order, 1901; (2) Callington Light Railway (Amendment) Order, 1909, further amending the Callington Light Railway Order, 1900, as amended by the Callington Light Railway (Extension of Time) Order, 1903, and the Callington Light Railway (Amendment and Transfer) Order, 1907, and authorising the construction of a light railway in extension of the light railway authorised by the Callington Light Railway Order, 1900.

Digitized by Google

MISCELLANEOUS CITY NOTES

MONTREAL WATER AND POWER CO.—It is announced that the letters of allotment have been posted for the issue of £100,000 4½ per cent. prior lien gold bonds, on behalf of the Montreal Water and Power Co., the underwriters being entirely relieved.

ANGLO-AMERICAN TELEGRAPH CO.—After placing £10,000 to the renewal fund for the half-year to December 31st, the directors recommend a balance dividend of 19s. per cent. upon the ordinary shares, a balance dividend of £1 10s. per cent. on the preferred stock for the year ended December 31st, and a first and final dividend of 8s. per cent. on the deferred stock for the year 1908. After paying these dividends there will be a balance of about £1,565 to be carried forward. The above dividends, together with those already paid, will amount to £3 4s. per cent. on the ordinary consolidated stock, £6 per cent. on the preferred stock, and 8s. per cent. on the deferred stock for the year 1908. For the year 1907 the dividend on the deferred stock was £1.

ANGLO-ARGENTINE TRAMWAYS CO.—An issue of £3,487,444 four per cent. debenture stock, ranking *pari passu* with £565,000 stock already issued, is being made by the Law Debenture Corporation at 90. The stock now offered is part of an issue limited to £4,465,674, of which £565,000 has already been issued, and £413,230 will be reserved for the conversion of the existing six per cent. debenture stock of the company, on terms which have been sanctioned by the Court. The stock is secured by a trust deed creating a floating charge (with provisions precluding the company from creating any mortgage or charge in priority to or *pari passu* with the stock) on the undertaking and assets of the company, subject only to an annual payment for 80 years from January 1st, 1905, to the City of Buenos Ayres Tramways Company (1904), Limited, of £71,060, reducible in certain events to £70,660. The issue is for the purpose of purchase or redemption of the debentures or debenture stocks of the five Buenos Ayres tramway companies which have been or will be acquired.

CHISWICK ELECTRICITY SUPPLY CORPORATION.—The General Investors and Trustees, Ltd., are offering £60,000 four and a half per cent. first mortgage debenture stock of the Chiswick Electricity Supply Corporation at 95. The stock constitutes a first charge on the undertakings of the company both at Chiswick and Aberystwyth. The trust deed provides that no mortgage or charge shall be created ranking *pari passu* with the stock now offered.

RIO DE JANEIRO TRAMWAY LIGHT AND POWER CO.—During the eleven months ended November last the net earnings of this company, says *The Stock Exchange*, amounted to £514,700, an increase of £123,000, and it may be safely assumed that the net earnings for the whole of 1908 totalled not less than £565,000, of which about £340,000 will have been required to meet the interest charges on the two debenture issues, leaving a surplus of approximately £225,000 at the directors' disposal. Such a sum is equivalent to over 4½ per cent. on the share capital outstanding, and far exceeds any previous achievement of the company.

BRITISH COLUMBIA ELECTRIC RAILWAY CO.—A dividend of 5 per cent. per annum has been declared on the preferred ordinary stock for the half-year ended December 31st, together with an additional dividend at the rate of 1 per cent. per annum for the same period.

BUENOS AYRES GRAND NATIONAL TRAMWAYS CO.—An interim dividend of 2s. 6d. per share, less income tax, has been declared on the 5 per cent. cumulative preference shares.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—A dividend of 5 per cent. per annum has been declared upon the preference shares for the December half-year, carrying forward £150 to reduction of electrical equipment account and £496 forward.

MEXICAN LIGHT & POWER CO.—The Mexico Tramways Co. having acquired a controlling interest in the Mexican Light & Power Co., the directors intend, says the *Financial News*, to propose at the latter general meeting, to be held in February, the following gentlemen, amongst others, as directors of the Mexico Light & Power Co., all of whom have consented to act:—Sir William Van Horne, Montreal, Chairman of the Canadian Pacific Railway; Messrs. George Flett (London Managing Director of Dick Kerr & Co.); Julio Limantour, of Mexico (a director of the National Railway Co. of Mexico and of the National Bank of Mexico); E. R. Wood, Toronto (a director of the Canadian Bank of Commerce); Walter Gow, Toronto (of Messrs. Blake Lash & Cassells); Dr. F. S. Pearson, of New York (President of the Mexico Tramways Co.); and Mr. R. C. Brown, Mexico (Managing Director of the Mexico Tramways Co.).

Industrial Banks in Germany.—Some time ago an industrial bank was founded by the various Siemens companies, and the Allgemeine Elektricitäts Ges. for the purpose of providing capital for electrical undertakings. A similar bank arranged by the Lahmeyer companies was been registered at Cologne with a capital of approximately £1,250,000. Loans will be granted by these concerns to the German Government, any of the States or any municipal or other public body offering absolute security.

NEW COMPANIES

NORTHERN ALUMINIUM CO.—This company was registered on January 4th, with a capital of £1,000 in £1 shares, to carry on any business relating to the winning and working of aluminium, sodium, or iron, and the production, manufacture, preparation, and treatment of such metals, &c. Private company. The number of directors is not to be less than two nor more than five; the first are not named. Registered office, Caxton House, Victoria Street, Westminster.

MIDLAND AGENCIES.—This company was registered on January 4th, with a capital of £2,500 in £1 shares, to carry on the business of engineers, electric lighting contractors, founders, tool-makers, woodworkers, builders, ironmongers, machinery brokers, &c. Private company. The number of directors is not to be less than two nor more than five; the first are to be appointed by the subscribers. Qualification, £100. Remuneration, £50 each per annum (charge £75). Registered office, 42 Summer Row, Birmingham.

CONSOLIDATED ELECTRIC WORKS & APPLIANCES.—This company was registered on January 7th, with a capital of £5,000 in £1 shares, to adopt an agreement with W. Murch, and to carry on the business of electrical engineers, electricians, suppliers of electricity, manufacturers of electrical apparatus, &c. Private company. The number of directors is not to be less than two nor more than seven; the first are T. Ward and W. Murch. Qualification (except first directors) 100 shares. Remuneration (except managing director), one guinea each per board meeting attended. Registered by C. Doubble, 14 Serjeant's Inn, E.C.

MOTOR & INDUSTRIAL ENGINEERING CO.—This company was registered on January 2nd, with a capital of £10,000 in £1 shares, to carry on the business of mechanical, electrical, and general engineers, manufacturers of and dealers in motor vehicles, magnetic, electric, telegraphic, telephonic, and other apparatus, &c. Private company. Table "A" mainly applies. Registered office, 4 Union Court, E.C.

STANDARD CABLE MANUFACTURING CO.—This company was registered on January 2nd, with a capital of £10,000 in £10 shares, to carry on the business of manufacturers and sellers of wires, cables, and other articles and accessories required in the electrical and allied trades. Private company. The number of directors is not to be less than two nor more than five; the first are C. N. W. A. Weuste, E. C. Carp, A. C. F. Haniel, T. Croon, and F. Plutte (managing director). Remuneration as fixed by the company. Registered office, 18–19 Queenhithe, S.E.

CAPETOWN-CAIRO RAILWAY & TELEGRAPH COMBINATION SYNDICATE.—This company was registered on January 6th, with a capital of £20,000 in £100 shares, with objects as indicated by the title. Private company. The number of directors is not to be less than two nor more than five; the first are F. Gheel Gildemeester, F. R. Wilm, and R. Poeppel. Qualification, £100. Remuneration of chairman, 50 guineas per annum; of other directors, as fixed by the company. Registered office, Broad Street House, New Broad Street, E.C.

DISTRICT ELECTRIC CO.—This company was registered on January 11th, with a capital of £3,000 in £1 shares (2,000 6 per cent. preferred), to take over the business of electrical engineers carried on at 39 Berry Street, Wolverhampton, as the "District Electric Co.," and to adopt an agreement with L. S. Aldridge. The subscribers are:—L. S. Aldridge, 27 Valentine Road, King's Heath, electrical engineer; L. K. Mason, 22 George Street, Edgbaston, electrical engineer. Private company. The number of directors is not to be less than two; the first are L. S. Aldridge and L. K. Mason (both permanent). Qualification 200 shares. Registered office, 39 Berry Street, Wolverhampton.

ROWLAND & HULTON.—This company was registered on January 12th, with a capital of £500 in £1 shares, to take over the business of an electrical and general engineer, and contractor, carried on by G. A. Wheeler, as H. Rowland & Co., for £75, payable in ordinary shares. The subscribers are:—G. A. Wheeler, 28 Barbican, E.C.; E. A. Good, 11 Southwark Street, S.E.; W. A. H. Hulton, 31 Brookfield, West Hill, Highgate, N.; R. P. Hulton, 31 Brookfield, West Hill, Highgate, N. Private company. The number of directors is not to be less than four; the first are G. A. Wheeler, E. A. Good, W. A. H. Hulton, and R. P. Hulton (managing director for one year from date of incorporation). Remuneration of managing director not more than £150. Registered office, 28 Barbican, E.C.

MANAOS TRAMWAYS & LIGHT CO.—This company was registered on January 12th, with a capital of £300,000 in £1 shares, to adopt an agreement with Antonio de Lavandeyra, and the Municipal & General Properties Syndicate, Ltd., to acquire any tramways, railways, or running powers, licences, rights, or easements, and to carry on the business of manufacturers and repairers of, and dealers in, railway, tramway, lighting, electric, magnetic, galvanic, and other plant and apparatus, rolling stock, vehicles, &c. Minimum cash subscription, seven shares. The number of directors is not to be less than three nor more than seven; the first are W. C. Burton, 9 Cloak Lane, E.C.; G. M. Booth, Adelphi House, Adelphi Terrace, Strand, W.C.; and J. Mitchell, Claudjes Hotel, Grosvenor Square, W. Qualification £500. Remuneration, £150 each per annum (chairman, £250).

Digitized by Google

DUMFRIES ELECTRICITY SUPPLY CO.—This company was registered in Edinburgh on January 7th, with a capital of £40,000 in £1 shares, to acquire and work the undertaking authorised by the Dumfries Electricity Supply Order, to adopt an agreement of sale with the India Rubber, Gutta Percha & Telegraph Works Co., to construct, repair, and maintain dynamos, accumulators, cables, wires, apparatus, lamps, and works, and to carry on the business of generators and suppliers of electricity, electrical and mechanical engineers, &c. The subscribers are :—W. E. Gray, 8 Moidan Road, Blackheath, London, civil engineer; R. N. Moir, 5 Lyncroft Gardens, Hampstead, London, secretary to public company; S. A. Russell, 22 Coventry Road, Ilford, Essex, civil engineer; E. C. Danberry, 40 Edwardes Square, Kensington, London, civil engineer; Talfourd Ely, Golden Hill Cottage, Hampstead, London, electrical engineer; S. E. Marsham, 22 Chester Square, London, gentleman; A. P. Crouch, Station Road, Chorley Wood, Herts, electrical engineer. The first directors are W. E. Gray, R. N. Moir, and S. A. Russell. Registered office, Leafield Road, Dumfries.

BALCKE & CO.—This company was registered on December 31st, with a capital of £5,000, in £1 shares. The objects are to take over the business of engineers carried on by Balcke & Co. at 27 Clement's Lane, E.C. Private company. Table "A" mainly applies. Registered office, 27 Clement's Lane, E.C.

BALFOUR, BEATTY & CO.—This company was registered on January 12th with a capital of £75.000 in £1 shares, of which 5.000 are preference shares. Its objects are to adopt an agreement with George Balfour & A. H. Beatty, and to carry on the business of contractors, engineers, concessionaires, builders, financiers, &c. The signatories are :—George Balfour, 9 Cloak Lane, Cannon Street, E.C.; A. H. Beatty, 9 Cloak Lane, Cannon Street, E.C. First directors (not less than two nor more than four) :—George Balfour and A. H. Beatty. Registered address, 22A College Hill, E.C.

FRANK LITTLE & CO.—This company was registered on January 18th, with a capital of £7,000 in £1 shares, to take over the business of motor, electrical and general engineers, agents, and garage proprietors carried on by F. Little and F. W. Cawthorn in Newcastle-on-Tyne and elsewhere as "Frank Little and Co." The subscribers are :—F. Little, 24 Moorside, Fenham, Newcastle-on-Tyne, engineer; F. W. Cawthorn, 30 Curtis Road, Fenham, Newcastle-on-Tyne, engineer. Private company. The number of directors is not to be less than two nor more than five. The first are F. Little and F. W. Cawthorne (managing directors, both permitting, subject to holding 500 shares). Remuneration of managing directors, £200 each per annum. Registered office, College Avenue, Newcastle-on-Tyne

P. & O. Batti-Wallahs' Society.—Mr. C. L. Lichtenberg, of the Kensington & Knightsbridge Electricity Supply Co., has been elected President of the P. & O. Batti-Wallahs' Society for 1909. The membership has been increased by 35 members during the year, the total now standing at 121.

Sale of Electricty by Private Persons.—In December, 1906, Mr. Walter Gibbons, on behalf of the Empire Palace, Ealing, Ltd., entered into a contract with the Ealing Corporation for a supply of electricity at the Empire Palace. Part of the premises were subsequently let to Messrs. Lipton, Ltd., who were supplied with energy by Mr. Gibbons. This supply was protested against by the Ealing Corporation, who took action to prohibit it, and the Brentford magistrates decided that Mr. Gibbons was acting illegally. The case, however, came before the Appeal Court last week, and the Lord Chief Justice confirmed the decision of the magistrates. He did not think that Mr. Gibbons was acting in any other way than under a misapprehension of the law on the point. The appeal was, therefore, dismissed with costs.

The Accident on the Liverpool Overhead Railway.—The Board of Trade report of Col. E. Druitt on the accident which occurred at the Seaforth Sands station of the Liverpool Overhead Railway on December 19th last has now been issued. A train had collided with the buffer-stop at the end of the station, and the rear bogie of the leading coach was derailed. One passenger was seriously injured, and other slight injuries were reported. It appears that the driver of the train was not a regular driver, although he was accustomed to take trains to and from the sheds, but had been sent for and put in charge of the train on account of the drunkenness of the regular driver. He had applied the Westinghouse brake, at first lightly, and then released it in order to pull up with the hand-brake in accordance with the regulations for entering termini. The rails were greasy, and the application of the Westinghouse brake by the guard, who noticed that the speed at this point was rather high, caused the wheels to skid to such an extent that it was impossible to pull up, as no further opening of the brake valve produced any effect, and the train ran into the hydraulic buffer-stops at about six miles per hour. The driver also attempted to reverse the motor, but the circuit-breaker came out. Col. Druitt considers that the error in entering the station too fast, considering the state of the rails, was due to over-confidence in himself, and not to want of knowledge. As these motor-coaches have no sanding arrangements, he thinks that it would be well to sand the rails in terminal stations when the rails are in a greasy condition.

COMPANY MORTGAGES

Particulars of the following mortgages and charges have been filed :—

OMEGA ELECTRIC LAMP CO.—£1,500 debentures, created December 18th, 1908, have been filed pursuant to Section 10 (3) of Companies Act, 1907, the amount of the present issue being £1.000. Property charged—The company's undertaking and property, present and future, including uncalled capital. No trustees.

NAIROBI ELECTRIC POWER & LIGHTING CO.—Issue on December 23rd of £1,000 debentures, part of series created April 8th, 1908, to secure £4,000, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Previously issued of same series, £2,500.

HAVANA TELEPHONE SECURITIES CO.—Debentures created by resolution of December 2nd, 1908, to secure not more than £246,250, have been filed, pursuant to Section 10 (3) of the Companies Act, 1907, the amount of the present issue being £126,880 6s. 3d. Property charged—First mortgage debentures of the Havana Telephone Co. (acquired in exchange for debentures of this issue), said debentures being deposited with Martin's Bank, Ltd. No trustees.

CHISWICK ELECTRICITY SUPPLY CORPORATION.—Trust deed dated December 8th, 1908, to secure £100,000 debenture stock. Property charged—Freehold and leasehold buildings at Aberystwyth, leasehold premises at Chiswick, the benefit of two provisional orders, and the company's general assets, present and future, including uncalled capital. Trustees—General Investors and Trustees, Ltd., 75-6 Lombard-street, E.C.

ARC LAMPS, LTD.—Particulars of £5.000 debentures created December 18th, 1908, have been filed pursuant to Section 10 (3) of the Companies Act, 1907, the whole amount being now issued. Property charged—The company's general assets, present and future, including uncalled capital. No trustees.

ELECTRIC IGNITION CO.—Particulars have been filed of £1.000 third debentures, created December 30th, 1908, and secured by trust deed of even date, the whole amount being now issued. Property charged : Royal Wellington Works, Sampson Road North, Birmingham, and the company's undertaking and other assets, present and future, except uncalled capital. Trustees : F. Lewis and Constance Hall.

ADAMS MANUFACTURING CO.—Particulars of £15,000 debentures, created January 4th and secured by trust deed dated January 8th, 1909, filed pursuant to section 10 (3) of the Companies Act, 1907, the amount of the present issue being £7,500. Property charges—The company's undertaking and assets, present and future, including freehold land and buildings in Bedford and leasehold premises in London. Trustee—Sir John L. Harrington and L. Hardy.

HARROW ELECTRIC LIGHT & POWER CO.—Particulars of £25.000 debentures, created January 1st, 1909, filed pursuant to section 10 (3) of the Companies Act, 1907, the whole amount being now issued. Property charged—General assets (subject to existing mortgage). No trustees.

NEW PUBLICATIONS

The Electrical Equipment of Collieries. By W. Galloway Duncan and David Penman. (London : Scott, Greenwood and Son.) Price 10s. 6d.

"Vectors and Vector Diagrams applied to the Alternating-current Circuit." By W. Cramp and C. F. Smith. (London : Longmans, Green & Co.) 7s.

Northampton Institute Conversazione.—The annual prize distribution and conversazione will be held on Friday and Saturday, February 5th and 6th. The Right Hon. the Earl of Halsbury has kindly consented to distribute the prizes on February 5th, and after the prize distribution the new buildings will be formally declared open. These buildings contain lecture-rooms, class-rooms, staff-rooms, rooms for the meetings of societies connected with the Institute, and extensive additions to the workshops and laboratories of the mechanical engineering department. The conversazione of members and students will be held on the following evening in both buildings.

Accident on the Lancashire & Yorkshire Railway.—A collision between two electric trains, which resulted in an outbreak of fire and the destruction of six coaches, occurred on the Liverpool and Southport section of the Lancashire & Yorkshire Railway on Thursday last, in a dense fog. It appears that a Southport train was held up by a signal just before entering the fifth station after Liverpool, and another train from Liverpool collided with it. Few passengers were in the trains, and fortunately none were seriously injured. The coaches caught fire, however, and four were completely and two partially destroyed. A train from Southport, which came to a standstill alongside, also caught fire, but all the passengers left without trouble. The driver of the second train was injured, and five or six passengers are said to be slightly hurt. According to the daily Press, the fire was due to electrical causes, but the railway authorities have refused to disclose the results of their inquiry into the accident.

"Electrical Engineering," although the Cheapest Electrical Paper (Price **1d.** weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

In his third and last lecture before the Royal Society of Arts on Power Supply in the United Kingdom, Mr. G. L. Addenbrooke commenced by describing the modern distributing system. In connection with the protection of mains, he advocated the adoption of the balanced transformer system. With regard to future developments, he looked forward to the time when the gas engine, supplied with gas from producers consuming bituminous coal, would be able to compete successfully with the steam engine. Such a development, however, could be retarded, he thought, by effecting further economies in steam plant. In conclusion, the lecturer dealt briefly with the legal position. (Page 106.)

Under the Potteries Federation scheme, the electricity undertakings of the Burslem, Hanley, Longton, and Stoke Councils will be carried on as separate undertakings, but they may be combined, if necessary in the interest of economical working. (Page 106.)

Special arrangements for removing and reinserting the contact ploughs of the cars of the London County Council's Tramways are provided at the ends of the Camberwell and Brixton section (which is equipped on the overhead system) to permit of through running. (Page 107.)

In consequence of the attitude of the Board of Trade concerning the proposed sale of the Bath Corporation electricity works, the Electricity Committee have recommended that the negotiations with Mr. Schenk be abandoned, and steps taken, if necessary, to oppose the Bill now before Parliament to confirm the agreement between the Corporation and Mr. Schenk. (Page 108.)

We give a description of the working of the "Angold" magazine flame arc lamp, with some details of the mechanism. This lamp burns for over 50 hours with the nine pairs of carbons contained in the magazines. The changing of the carbons is effected in a few seconds. A forced feed of the carbons is provided, and by an ingenious mechanical device, the movement of the cross-bar is reversed when one pair of carbons is nearly consumed, so that the bar works up to the top again to engage with the new pair of carbons. (Page 109.)

A Paper read last week by Dr. E. Rosenberg at

Digitized by Google

Manchester and in London, dealt with hunting troubles in the parallel operation of alternators. The author explained the magnifying effects of the electrical reaction of an alternator on the oscillations produced by those irregularities in the torque diagram which were not taken care of by the flywheel, and he gave some curves which showed the critical values of the flywheel effect for given electrical constants, as a function of the speed. The author pointed out that the dangerous conditions could be avoided by either increasing the flywheel effect or by improving the regulation of the alternator. In very slow speed engines, very often the only possible way was to reduce the initial oscillations to the smallest possible value, and to apply amortisseurs to the alternator. In the London discussion Mr. Stoney called attention to the part played by the governor in causing hunting of turbo-alternators. Mr. Clough doubted the value of dampers. The importance of proper valve setting was emphasised by Mr. Howe, and Dr. Thompson said that one conclusion to be drawn from the Paper was that no alternator should be driven by engines running at less than 100 r.p.m. Mr. Sayers and the President also spoke, and Dr. Rosenberg replied. There was also a discussion in Manchester. (Page 110.)

THE local electrical contractors of Aberdeen have refused to assist the Corporation in the promotion of an electrical exhibition on account of the present high charges for electricity supply.—A report has been presented to the Cardiff Corporation showing that the cost of putting the tramway track into thorough repair would be £11,175.—The Chairman of the Salford Electricity Committee and several other members have resigned owing, it is stated, to the recent criticisms upon what have been termed "secret contracts" for the supply of electrical energy.—A deputation from the Sheffield Corporation is now on the Continent inspecting the trackless trolley system.—The price for the purchase of the Morecambe horse tramways by the Corporation has been fixed at £13,391. (Page 115.)

AN overhead travelling crane is required at Clacton, and electrical stores at Portsmouth, Leeds, Ilford, and Paddington.—Large quantities of telephone material are being advertised for by the Australian Commonwealth Postmaster-General's Department.—Local Government Board inquiries have been held at Reigate (£4,000) and Morley (£11,759). The Westminster Electric Supply Corporation, Ltd., require high- and low-tension switchboards and boosters. (Page 116.)

THERE is a balance of £127,534 upon the working of the Metropolitan Railway for the December half-year, and after meeting dividends on preference shares a dividend of 10s. per cent. is recommended upon the ordinary shares. The report of the Dublin United Tramways Co. for the year to December 31st shows a balance of £43,249, and the directors recommend a 6 per cent. dividend on the ordinary shares. Dividends of 3½ per cent., 4 per cent., and 2½ per cent. are recommended by the directors of the Central London Railway Co. upon the various classes of shares. A dividend of 3 per cent. is recommended upon the ordinary shares of the London Electric Supply Corporation. The net revenue of the Great Northern & City Railway Co. for the December half-year is insufficient to meet the fixed charges by £5,596. After meeting the preference dividend the accounts of the Liverpool Overhead Railway Co. for the December half-year show a balance of £4,210, which is carried forward. (Page 118.)

AMONG the Patent Specifications published by the Patent Office on Thursday last was one by W. Schäffer for a continuous-current transformer for delivering at constant voltage or constant current. S. R. Ridgway and C. M. Brunt have patented a spring fastener for connecting leads to terminals, and the British Thomson-Houston Co., an automatic motor-starter. Another specification by the British Thomson-Houston Co. refers to an improvement in a previously patented support for metal filaments. A specification by H. Helberger describes an electric furnace in which the graphite crucible forms part of the secondary circuit of a transformer. A. Wolff has patented a compound wire for alternating-current work where high self-induction without skin effect is required. Means for safeguarding against arcing due to damaged cables in mines are described in a specification by the Land und Seekabelwerke Akt.-Ges., and another by W. C. Arsem relates to the manufacture of tungsten filaments. Among the patents expiring during the current week is one communicated to the British Thomson-Houston Co. by E. D. Priest for a double-barrel traction motor controller. Short abstracts of the above specifications, and a classified list of the specifications published to-day, are given in our Patent Record. (Page 121.)

A NEW instrument designed by Prof. B. Hopkinson and Mr. Thring for measuring the power transmitted through turbine and other shafts by observing their torsion has been put on the market. (Page 122.)

A LARGE amount of delay in the telephone exchanges has been caused by the present public call-box procedure, as, after the required subscriber has been rung up, the caller often fails to produce the necessary pennies at once. We describe a new arrangement, which has been used tentatively by the National Telephone Company and more recently by the Post Office, to prevent this delay. The coins have to be inserted in the money-box before the exchange can be called up, but they are returned to the caller if the call is ineffective. (Page 122.)

A DESIGN of hand-wound time switch and a terminal box designed for motors mounted on slide rails are described in short articles. (Page 124.)

A LETTER from Mr. L. H. Walter refers to the part played by wireless telegraphy in the saving of the passengers of the *Republic*, and, emphasising the necessity for accurate observations of direction, points out the capabilities of the Bellini and Tosi system in this respect. A correspondent writes giving his views as to the ideal requirements of a surface contact system. (Page 126.)

ONE of the difficulties which we anticipated in the practical working of the revocation clause in the new Patents Act has now received serious consideration by the London Chamber of Commerce. When a patent has existed for four years without having been worked in this country it does not automatically become void, but a petition for its revocation must first be made to the Comptroller, and the procedure that follows entails a certain amount of expense on the petitioning party. If, as will usually be the case, not only the petitioning firm but also a number of its trade competitors will benefit by the revocation of the patent, there will doubtless often be some difficulty in finding a firm which will come forward and incur the trouble and expense of the proceedings by itself. To facilitate joint action in the matter the London Chamber of Commerce has drafted the following resolution, which will be submitted to the general meeting of the Association of Chambers of Commerce of the United Kingdom to be held at the Whitehall Rooms, Hotel Metropole, London, from March 2nd to 4th:—

That this Association, having regard to the provisions of the Patents and Designs Amendment Act, 1907, is of opinion that it is desirable to form a Committee or Association with the object of enforcing the Act in cases where such patents or processes are taken out in this country without being *bona fide* manufactured and carried on in the United Kingdom.

Digitized by Google

While we approve of the general object of the resolution, we cannot but think that it should contain a little more definite announcement of the policy to be followed. The powers of this Committee should be clearly defined, the sum of money which the Council of the Association is prepared to allot for fighting any particular case should be decided upon, and the outcome of the discussion upon the resolution should be that immediate steps are taken to form an active Committee with wide discretionary powers and the control of sufficient funds to make their work effective.

SEVERE critics of Dr. Rosenberg's Paper, read before the Institution of Electrical Engineers in London and Manchester, will say that his elaborate mathematical demonstration did little more than to emphasise the difference between British and German central station practice before the steam turbine became the recognised prime-mover. With large slow speed engines driving alternators, paralleling difficulties were experienced long after the more fortunate engineers with high-speed plant had almost forgotten that any instability in parallel running ever occurred. The Paper will, however, be of value to designers of large machines which are to be driven by gas engines, for, although there is already a general tendency towards higher speeds, the alternator that has to be used is a very different machine to the one which English designers have had to produce during the past few years. Perhaps we shall hear more of the subject when Mr. Andrews's forthcoming Paper on gas engines is discussed.

Accident on the Lancashire & Yorkshire Railway.—The Board of Trade inquiry into the accident which occurred on the Liverpool & Southport Electric Railway on January 21st, was held on Thursday last, and was conducted by Colonel Druitt, one of the Board's inspecting officers of railways, assisted by Mr. Trotter, the Board's electrical adviser. It will be remembered that the 7.20 train from Liverpool ran into the rear of the 7.10 train going in the same direction; the latter train was stationary at the time. J. Potter, the signalman at Marsh Lane Junction box, stated that he accepted the 7.10 train and passed it on to the Seaforth North box. He also accepted the 7.20 train, and, after speaking over the telephone with North Seaforth, passed it on, without, however, giving the usual bell signals to North Seaforth. This he took the full responsibility for. The evidence of the North Seaforth signalman confirmed this statement. T. Jones, the driver of the 7.10 train, stated that he put on the short-circuiting bar about half a minute after the collision, and, according to the sub-station attendants, all the circuit-breakers opened at the time of the collision. The cause of the outbreak of fire was not elicited at the inquiry.

Johannesburg Gas Plant.—In the Edinburgh Court of Sessions on Saturday last Lord Mackenzie pronounced judgment in an action by the Municipal Council of Johannesburg against D. Stewart & Co., Ltd., of Glasgow, and the representatives of the late Joseph Beardmore, Glasgow, claiming sums amounting to over £400,000 in respect of the defendants having failed to carry out contracts entered by them for the installation of gas-driven plant for the city of Johannesburg, for tramway, lighting, and power purposes. According to *The Standard*, the defendants pleaded that the matter should be dealt with by arbitration in England. They denied the alleged breach of contract, and stated that the installation was made according to the specification of the plaintiffs, and that any failure was due to the unsuitability of coal supplied. The defendants Beardmore were guarantors for the performance of the contract by the other defendants, their liability being limited to the amount of £115,134 contained in a bond. The plaintiffs sought repayment of the purchase price already paid to Stewart & Co., and about £200,000 as damages for the alleged breach of contract. Lord Mackenzie dismissed the action in so far as it was directed against Beardmore, and found that the arbitration clause relied upon by the defendants must be construed by the law of England. His lordship stayed procedure, in order that the parties might carry through arbitration proceedings in England, if on a true construction of the clause it was valid and covered the dispute in question.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 4TH.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Dr. Howard Pirie will open a discussion on "The Transport of Ions."

FRIDAY, FEBRUARY 5TH.

Northampton Institute.

7.30 p.m. Prize Distribution at St. John Street, Clerkenwell, by the Right Hon. the Earl of Halsbury, P.C.

SATURDAY, FEBRUARY 6TH.

Electrical Football League.

3 p.m. The following matches will be played :—Metropolitan Electric *v.* General Electric, at Acton Lane, Willesden; Ediswan *v.* St. Pancras Electric, at Wormholt Farm, Pitch No. 8.

Northampton Institute.

6.45 to 11 p.m. Annual Conversazione at St. John Street, Clerkenwell.

TUESDAY, FEBRUARY 9TH.

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Meeting at 207 Bath Street, Glasgow.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, Westminster, S.W. Papers to be read :—(1) "Applications of Electrolytic Chlorine to Sewage Purification and Deodorisation by the 'Oxychlorides' Process," by Dr. S. Rideal; (2) "A New Electrical Hardening Process," by E. Sabersky.

WEDNESDAY, FEBRUARY 10TH.

Association of Engineers-in-Charge.

8 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street. Paper to be read :—"Polyphase Motors for Driving Machinery," by H. B. Poynder.

THURSDAY, FEBRUARY 11TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, S.W. Paper to be read :—"Use of Large Gas Engines for Generating Power," by L. Andrews and R. Porter.

FRIDAY, FEBRUARY 12TH.

Physical Society.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute Road, when the Presidential Address will be delivered.

Accident in a Mine.—An inquiry was held at Dunfermline on Thursday last into the circumstances attending the death of a labourer named Beveridge, who was killed by contact with a live cable in the Fife Coal Co.'s Aitken Pit, Kelty, in December last. The jury found that death had been caused by contact with an imperfectly insulated cable, the part in question being a badly repaired joint. They expressed the opinion that proper precautions had not been taken to inform the workmen of the danger, and recommended that notices should be placed in mines prohibiting unauthorised person from touching the cables or plant.

Euston-Watford Electric Railway.—As we have previously announced, the contract for the construction of the Watford junction of the new electric railway from Euston to Watford has been let by the London & North-Western Railway Co. to Messrs. C. Brightman & Sons, of Watford. The line, which has a total length of 23 miles, will be in tunnel from Euston to Kilburn, whence it will follow the London & North-Western main line on the surface to Bushey, and then alongside the Rickmansworth branch to Watford. At Euston the tunnels will be on either side of the station, the trains passing in on the one side and round a loop to the departure platform on the other side, thus avoiding all shunting.

Wireless Telegraphy.—It is announced by the General Post Office that radiotelegrams can now be sent through the North Foreland station to the following ships on the Queenborough-Flushing route :—*Duitschland*, *Engeland*, *Koningin Regentes*, *Koningin Wilhelmina*, *Nederland*, and *Prins Hendrik*. The charge is 3½d. a word, with a minimum of 2s. 1d. a telegram, for the wireless service, plus the ordinary inland rate. According to the daily Press, a large wireless station is being erected on the Lincolnshire coast near Humberstone. It is stated that nine masts have been put up, the centre one being 180 ft. high and surrounded by four shorter ones, and another four outside these latter.

ELECTRIC POWER SUPPLY IN THE UNITED KINGDOM

THE third and last of the three Cantor lectures on the above subject was delivered on Monday evening last by Mr. G. L. Addenbrooke at the Royal Society of Arts. It will be remembered that in the second lecture the working costs of large supply undertakings were compared with those for a private supply, and that the general design of power stations was then dealt with, great importance being attached to the possibility of effecting economy in the boiler-house. In the last lecture Mr. Addenbrooke commenced by considering the distributing system. Lead-covered paper cables were, he said, universally used for distribution at pressures of from 6,000 to 20,000 volts. Approximate costs of such cables, including laying in conduits, were given in Table V. There was no doubt that further study of the subject of resonance would lead to methods of rendering these effects negligible, and in that case the thickness of insulation and the diameter of the lead covering of cables could be considerably reduced with a consequent material reduction in the cost of such cables.

Table V.—*Cost of Distributing Mains.*

Section of cable. Sq. in.	Approx. capacity in kw.	Cost per mile. £	Cost per kw. capacity per mile. Shillings.
0·05	750	900	22·0
0·10	1,500	1,200	16·0
0·20	3,500	1,700	10·5

In the more open districts overhead mains were being used; the cost was about half that for cables, and as faults were readily localised and repaired, there was less necessity for duplicate lines. Pressures up to 30,000 volts were employed in this country. The usual spans were 40 yards to 50 yards. In laying out a distributing system it was advisable to arrange this as far as possible in loops so that every customer might be approached in two ways, while there was as little duplication of cables over the same route as possible. In case of a fault, only the damaged section need be isolated, and all the customers could be supplied from one or the other end of the loop while repairs were being effected. With regard to the transformers, the efficiency under load averaged as high as 97·5 per cent., and the no-load losses could be kept very low indeed. The smaller transformers cost about £2 per kw., 50 kw. sizes about £1 10s. per kw., and the 100 kw. sizes about £1 per kw. Very large transformers, such as 500 kw., would not average more than 10s. per kw. In some cases it paid to use double transformation first from 20,000 to, say, 3,000 volts in a sub-station, and then from 3,000 volts to the motor pressure on the consumer's premises.

The lecturer then mentioned the advantages to be gained by the use of subsidiary power stations, as were employed on the Newcastle power companies' distributing system (see ELECTRICAL ENGINEERING, Vol. IV., pp. 505 and 523, and the issue for January 14th, 1909, p. 38), and referred to the small Diesel engine stations used on the Charing Cross Co.'s mains in London for the purpose of meeting sudden loads due to fog, &c. With respect to the various methods which have been devised for localising and isolating faulty sections on distributing networks, the lecturer described briefly the Merz-Price system (see ELECTRICAL ENGINEERING, Vol. III., p. 763), but pointed out that, though this system was of considerable use on single cables, it was by no means perfect, especially in complicated systems. A, in some respects, better, but more expensive, system was that known as the balanced transformer system of mains protection. This necessitated the laying of a small three-core pilot cable alongside the main cable between the sub-stations. In the lecturer's opinion, the latter would be the system adopted on complicated networks, as it had the great merit of cutting out the faulty section on one side of a customer only, which enabled the supply to be continued from the other side of the loop. The action of this system was briefly as follows :—Series transformers were placed on the three main cables entering and also leaving any sub-station, and the secondaries were connected to three pilot wires. At the next sub-station the pilot wires were joined to the secondaries of another set of three series transformers, but arranged so that the two induced pressures were in opposition. As long as the main cables were in good condition, no current passed through the pilot wires, but if a fault developed the induced pressures would not balance, and a current would flow along a pilot wire. This current operated a relay, which in turn opened the oil switches at both ends of the section. The lecturer then showed a number of slides illustrating modern patterns of high-tension switchgear, and drew special attention to the ironclad type developed by Messrs. Reyrolle & Co., and used on the Newcastle Co.'s mains (see ELECTRICAL ENGINEERING, Vol. IV., p. 24).

Turning to the advantages to be gained by electric driving, Mr. Addenbrooke referred to the increased speed rendered possible in textile work by the very steady drive obtained with electric motors, as the threads could be run at the maximum strain. The application of electric driving to main haulage for collieries and to rolling mills was also mentioned. Many examples of the electric driving of textile mills were given, and the use of single-phase motors (with 50 per cent. speed variation by movement of the brushes on the commutator of a short-circuited armature) on three-phase supply circuits was referred to as one means of overcoming the objection associated with the employment of alternating-current motors, that speed variation could not be obtained.

Dealing with the probable development of public supply for power purposes, the lecturer mentioned that 10 h.p. motors were now procurable for £3 10s. per h.p., including starting gear, and 50 h.p. motors for £2 10s. per h.p. No private plant could be put down with such a low capital cost. If any remarkable developments were made in prime movers, it was more likely that the central station plants would be altered in accordance, than that numerous private plants would be erected, as the losses in distributing systems were comparatively low; they ought not to average more than 16 per cent., while the losses at full load even up to the consumer's motor would not average 10 per cent. With regard to the competition between gas and steam engines, Mr. Addenbrooke thought that economies to the extent of 25 per cent. could be effected in the working of steam plant if the matter were thoroughly investigated. These economies could be effected by savings in banking boilers, reduction of radiation losses, better regulation of air supply, use of hot air supply, higher degrees of superheat, improvements in auxiliaries, and economy in the turbines. Although the thermal efficiency of large gas engines was approximately twice that of a steam plant, they could only be used satisfactorily with gas free from impurities, and regular in quality such as that obtained from blast furnaces. The gas from producers consuming bituminous coal was difficult to purify and irregular in quality, and in consequence such gas plants, where gas was produced from coal, could not compete with steam plants. Again, although some 40 per cent. could be saved in coal, the total saving in running costs would only be some 10 per cent., and the extra capital cost would counterbalance this.

The lecturer then turned to a consideration of the legal position in this country, and emphasised the need of new legislation with regard to the methods of obtaining powers for the supply of electrical energy, and the relations between power companies and municipal authorities. As an example of the restrictions imposed upon the development of a supply system, the lecturer showed the map of the Lancashire Power Company's mains, given in ELECTRICAL ENGINEERING, January 28th, p. 87. In this map the shaded areas represented those from which the company was excluded. In connection with the application for Provisional Orders, Mr. Addenbrooke pointed out that it often took two to two and a half years after it had been determined to proceed with a supply before an undertaking could be got into actual operation, and suggested that there was no reason why the Provisional Order procedure should not be assimilated to the Light Railway procedure, which permitted application to be made twice in the course of the year.

THE POTTERIES FEDERATION SCHEME

THE Act of Parliament authorising the federation of the towns of Fenton, Hanley, Tunstall, Burslem, Longton, and Stoke-on-Trent into the county borough to be called Stoke-on-Trent, has now been issued. The section of the Act relating to the electricity undertakings, viz., Burslem, Hanley, Longton, and Stoke, states that these shall be maintained by the new borough as separate undertakings. Should it be deemed expedient, however, at any time in the interest of economical management, to combine two or more of the undertakings, this may be done with the consent of the Local Government Board. Before giving consent, a local inquiry shall be held by the Board upon application by not less than 200 consumers. It is also laid down that the revenue from the undertakings shall be applied in meeting establishment and running charges, sinking fund and interest charges, and, if thought fit, a yearly sum equal to 5 per cent. of the revenue to form a reserve fund, not exceeding one-tenth of the total capital expenditure. This merely repeats the conditions under which the undertakings are now carried on. Any deficiencies are to be made good out of the reserve fund, if it exists, otherwise, the rates are to be called upon; any sum so paid out of the rates is to be repaid from future profits.

THROUGH RUNNING BETWEEN THE CONDUIT AND OVERHEAD SYSTEMS ON THE L.C.C. TRAMWAYS

With the increasing extensions of overhead as well as conduit lines on the London County Council tramway system, the problem of linking up the sections of the lines where the systems are different, is one of some importance. At the present time, through running to and from a conduit line is only necessary in one of the three overhead sections of line equipped by the Council, as both the Woolwich and Hammersmith-Harlesden lines (*see* Electrical Engineering, Vol. III., page 879), are isolated. In the case of the line equipped on the overhead system from Camberwell to Brixton, however, provision has been made for removing and replacing the contact "ploughs" of the cars at the two ends of the section at the junction of Coldharbour Lane and Denmark Hill, and at the corner of Gresham Road and Brixton Road. Although the plough change points there installed may not represent the final form that will be standardised for future extensions, their arrangement is of interest as indicating the general lines of the method to be employed.

The general disposition of the track at the former of these points is shown in the sketch plan in Fig. 1. It will be seen that the conduit slot, both on the incoming and outgoing conduit lines, crosses the track

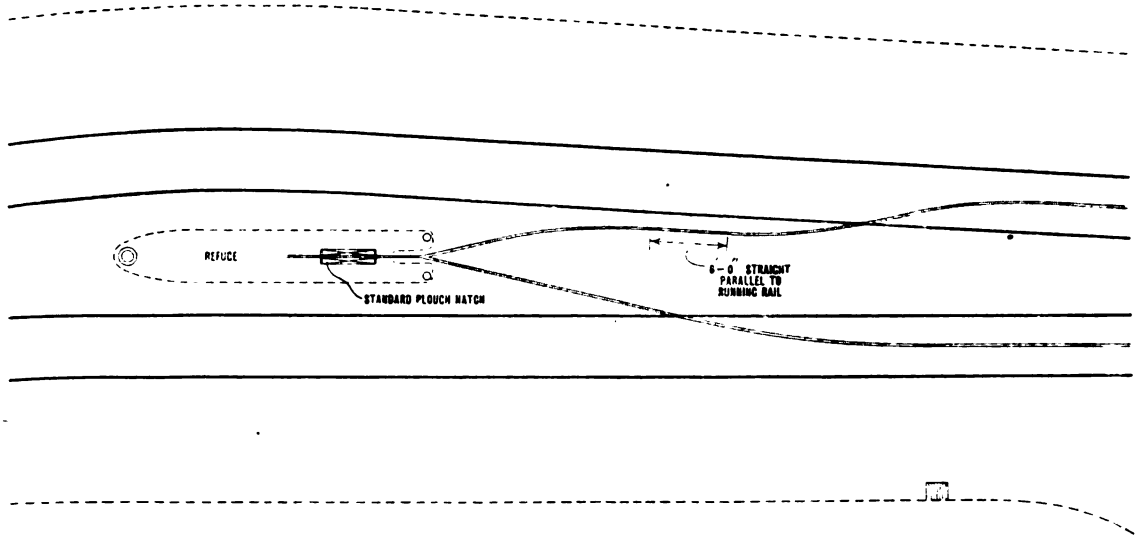

Fig. 1.—Sketch Plan showing Arrangement of Track and Conduit at Junction between Conduit and Overhead Lines at Corner of Denmark Hill and Coldharbour Lane.

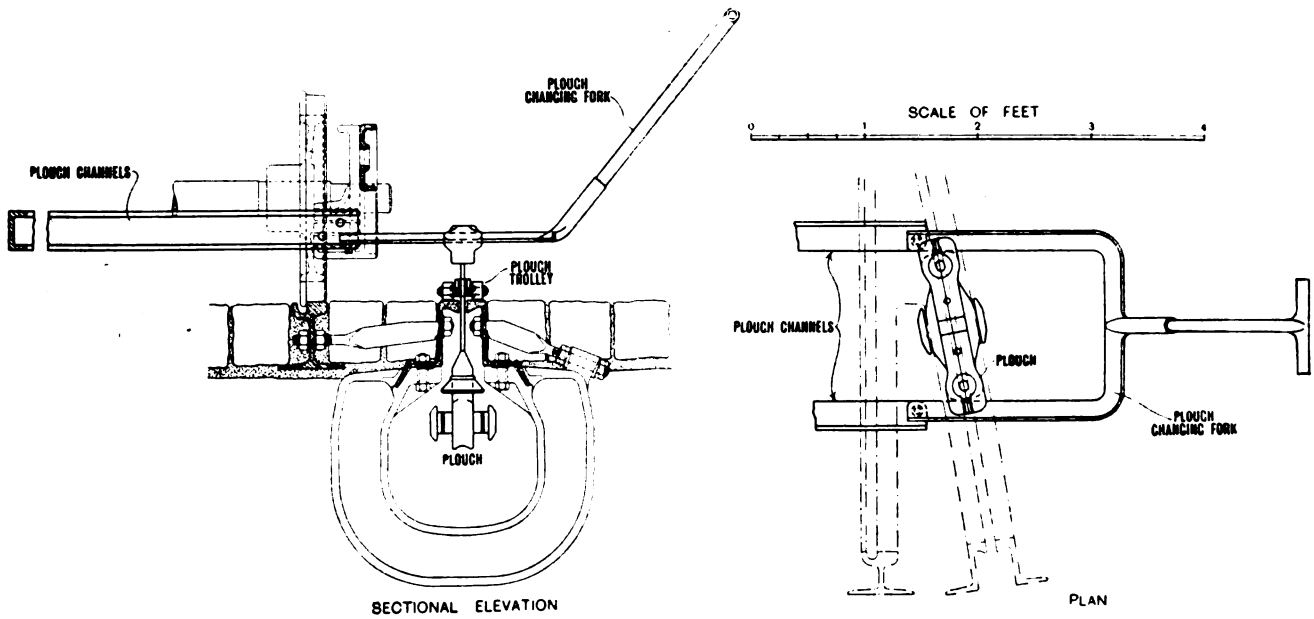

Fig. 2.—Plan and Section showing Plough in Conduit lifted off Wheeled Trolley by Plough Changing Fork and ready for Sliding into Position.

rails, and leads to a point protected by a refuge between the tracks. For a reason that will be seen below, the slot, when outside the track in the case of the outgoing line, runs for a short distance parallel to the track, but on the incoming side, where the ploughs are removed, this is not necessary. A standard plough hatch, where ploughs can be removed for examination or repair, and re-inserted in the conduit, is provided at the junction of the two slots at the refuge, but this plays no actual part in the usual routine of changing the ploughs.

The simpler of the two operations is the removal of the plough from a car leaving the conduit line. The

Digitized by Google

car is stopped in a position just short of the point where the slot crosses the track rail, and while the conductor is placing the trolley on the wire ready for proceeding, the attendant, or "plough-boy," reaches under the car and uncouples the two flexible leads connected to the plough, which are, of course, by this time dead, as the conduit conductors do not extend to this point. The car then proceeds, taking power from the trolley, and the obliquity of the slot simply slides

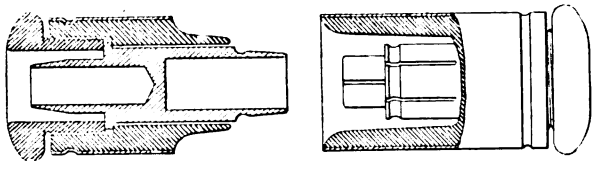

FIG. 3.—CONNECTION PLUG AND SOCKET FOR PLOUGH LEADS.

the plough sideways off the end of its carrier on to the little wheeled truck which has been placed for its reception, and leaves it clear of the car. When the car has passed on, the rejected plough is simply guided by hand to the slot junction, and shunted ready for a car on the other side.

At this point it may be said that the only alteration to the standard conduit car equipments, beyond the fitting of the trolley-base, boom, &c., and a change-over switch, is an alteration in the length of the plough leads to make the connectors more easily accessible. The actual form of the connecting plugs and sockets is shown in Fig. 3. On disconnecting the short leads attached to the plough, the longer car leads are hooked up out of the way on to a wire stretched for the purpose across the truck frame. There is no alteration whatever to the standard plough carrier. This consists essentially of a pair of transverse rails or channels, and is always arranged to give complete freedom of movement for the plough to follow the position of the slot right across the car, and contains no stop at the ends, so that when the slot passes outside the track, the plough simply slides off its rails. A form of spring contact is under consideration, in order to do away with the necessity for stopping to disconnect the leads.

The operation of re-inserting a plough on a car coming from the overhead section of the line is also quite simple, and occupies scarcely more than half a minute from the first stop of the car to its start off again with the plough coupled up. On the approach of a car a plough on its little truck is pushed to the part of the slot shown in Fig. 1, parallel to the running rail, where the car is stopped. The attendant then hooks the plough-changing fork with which he is provided into the plough channels, so that it virtually forms an extension to them, and levers up the plough off its trolley to the position shown in Fig. 2. The car then proceeds slowly while the attendant still holds up the handle of the fork, and the obliquity of the slot slides the plough on to its carrier. The car is then stopped, momentarily, the fork is removed, and the plough leads connected up. The car is then free to proceed, and as soon as it reaches the slot conductors, the trolley-boom is hauled down. The object of the straight portion of the outside slot is to diminish the necessity for accurate stopping, and to facilitate inserting the plough by having it parallel to the car.

Two or three ploughs are kept in reserve to prevent, through a delay in traffic, ploughs being called for before they have arrived.

In conclusion, we must express our thanks to Mr. A. L. C. Fell (Chief Officer of Tramways to the London County Council) for allowing us facilities for obtaining information, and reproducing drawings of the equipment. We wish also to acknowledge the help of Mr. Ireland (Rolling Stock Superintendent) who afforded much assistance to our representative.

THE PROPOSED SALE OF THE BATH ELECTRICITY WORKS

NEGOTIATIONS for the purchase of the municipal electricity works by Mr. Schenk, acting on behalf of the Somerset and District Electric Power Co., have failed owing to the attitude taken up by the Board of Trade in refusing to sanction the proposed transfer. In these circumstances, the Electricity Committee recommend :—"That the Council shall take the necessary steps for rescinding the agreement, and authorise the Town Clerk to serve the requisite notice in that behalf; and further, that if the City of Bath Electric Supply Bill and the Somerset and District Electric Power Bill are nevertheless proceeded with, the Town Clerk be instructed to take all necessary steps for enabling the Council to oppose the same in Parliament and to affix the Common Seal to all petitions and other requisite documents."

The facts of the negotiations were given in our issue for December 10th, p. 765, and may be briefly summarised as follows :—

The proposal was to transfer the undertaking to Mr. E. Schenk, representing the Bath and District Electricity Supply Co., the intention being subsequently to transfer the works to the Somerset and District Electric Power Co. The result of correspondence with the Board of Trade, however, was that the Board of Trade refused to proceed with the Provisional Order, for which an application had been made, to carry out the proposed transfer. It was contemplated that the transfer should take effect as from March 31st, 1908, at which date the capital expenditure upon the undertaking was £159,423, but the purchase price, as stated in the draft deed of transfer, was £162,939, a difference of £3,516. The deed of transfer also provided that the sinking fund and reserve fund, amounting together to £36,000, should remain the property of the Corporation, thus the Corporation contemplated making a profit on the sale of £39,516. The main objection was that the Board of Trade regarded it as contrary to practice on the transfer of an electric lighting undertaking that the undertaking should be charged with any profit accruing to the transfer, inasmuch as full price was being paid for plant which had been many years in use.

A deputation waited upon the Board of Trade in regard to this decision, and in view of the result of the meeting, which was private, the electricity committee, in spite of alternative proposals by Mr. Schenk, who desired to take the matter to Parliament, decided to put the above resolution before the Corporation.

Proposed New Electric Railway in Germany.—The Allgemeine Elektricitäts-Ges. and Siemens-Schuckert-Werke-Ges., have applied to the Prussian Ministry of Public Works for a concession to construct an electric railway between Cologne and Düsseldorf, a distance of 40 miles. It is proposed to accomplish the journey in 40 minutes. It is suggested that the trains should run at tramcar speed through the streets of each town, and pick up passengers at various points, instead of stopping at a terminus at each end of the journey.

Institution of Electrical Engineers.—The following is the list of candidates who were elected at the meeting on Thursday :—*Associate Members:* E. J. Johnson, T. G. Jones, M.Sc., W. G. P. MacMuldrow, D. N. Mallik, A. R. Oxley, Col. K. N. Rana, Lieut. E. G. Robinson, R.N., H. B. Stone, W. Walker, P. S. Wentworth, W. W. Wood. *Associate:* The Rev. F. W. R. Metcalf, M.A., R.N., *Students:* B. Abel, F. E. Allen, W. Bacon, F. Bailey, G. E. Bairsto, B.Sc., B. Eng., W. H. Barlow, A. E. Barter, R. H. Bartley, B. Batra, H. Bedson, R. Beeson, D. D. Belcham, H. D. V. Bindon, P. R. Blarney, H. Bond, H. C. Bowen, E. J. Brunning, E. V. Buchanan, M. A. Bulloch, W. B. Burford, G. S. Cattell, R. G. Cole, H. P. Coles, H. G. Dashwood, R. H. A. Deane, M. De Castro, J. A. J. De Mello, R. E. Dickinson, J. W. Dodds, W. Eccles, O. Evans, G. Y. Fraser, J. S. Geddes, A. B. Geddie, M. R. Ghadiali, A. O. Gilby, F. Goble, C. W. Goodram, J. H. Goodwin, G. Graham, D. H. Green, W. C. Griffith, D. H. Hammonds, C. G. Hawes, H. C. Healey, F. B. Holt, C. G. Huntley, J. C. Hutton, T. B. James, E. J. Jarvis, F. G. Ketelbey, E. P. Knill, E. P. Larkin, C. H. Lauth, S. W. Leslie, W. Logan, J. N. C. Luxton, P. A. McGee, D. J. McHatton, N. McPhee, E. Marks, R. O. Martin, C. N. Mathieu, W. Midgley, N. Mitchell, R. J. Owen, W. E. Owen, E. V. Pannell, J. Parkinson, G. W. Pearson, E. Peek, C. E. Penn, W. J. Picken, N. C. Pimm, H. W. Powell, R. H. Rawlinson, D. D. Rayner, E. L. Reinert, J. C. Rennie, C. L. Roberts, H. W. D. Rock, W. D. Roe, N. N. Roy, L. L. Ruderman, G. S. Seabrooke, R. B. Sennitt, A. R. Setna, W. Smethurst, A. H. Smith, S. L. Smith, A. C. Sparks, A. R. Stelling, R. Stephen, V. F. Stephens, K. Sung, H. K. Trechmann, B. A. Turkhud, J. M. Webster, H. T. Werren, J. R. A. Willey, D. S. Wood, W. A. Wood, W. A. Wordley, A. W. Wouldham, Le Hang Yaou, S. D. Zossenheim.

THE "ANGOLD" MAGAZINE FLAME ARC LAMP

ALTHOUGH the efficiency of the flame arc lamp expressed in watts per candle-power is much better than that of the ordinary enclosed arc, and the distribution of light also more effective, there are many points in which the former is distinctly inferior. Chief among the disadvantages of the flame lamp are the short burning life and the unsteadiness of the arc. To assist the arc in burning steadily, carbons of small diameter have been used, and the quick consumption of these necessitated a great length of carbon and consequently a long lamp in order to obtain a reasonable burning life. Again, to decrease the voltage drop in these long carbons it has been necessary to provide them with either metal cores or metallic coverings. This latter not only nearly doubled the cost of the carbons, but tended to render the arc less steady.

The "Angold" Flame Arc Lamp, which is manufactured by the General Electric Company at their arc lamps shops at Salford, is one of the lamps in which much ingenuity has been expended in overcoming these disadvantages. The burning life is increased from 50 to 55 hours by the aid of a magazine of carbons which are burnt in succession, and the use of carbons without metal cores or coverings is rendered possible, as contact is made close to the burning end. The length of the lamp is also not excessive, being only 38½ in. over all. Although this lamp has now been on the market for a year or more, and is burning satisfactorily in a large number of towns, improvements in the mechanism have been made from time to time, and a complete description of the lamp and its action as it is at present will no doubt be of interest to many of our readers.

The accompanying views of the interior of the lamp show the arrangement of the various parts. Fig. 1 represents a lamp for use with a differential cut-out and equivalent resistance separate from the lamp itself, and this is the best arrangement when contacts and lowering gear are used, as it gives complete independence from the other lamps in series. In the lamp illustrated in Fig. 3, on the other hand, the cut-out and equivalent resistance are inserted in the body of the lamp itself. The lamp mechanism is the same in both cases, and as the views of Figs. 1 and 3 are taken from opposite sides of the lamp they show the whole of the interior.

It will be noticed that the mechanism is in two distinct chambers, the lower containing only the magazines and the coarser working parts. The upper chamber contains the carbon-feeding and the arc-controlling gears, and the solenoid plungers also project into this chamber. There is only a small opening in the economiser, and any fumes that may rise into the lower chamber have very little chance of getting into the second chamber. Besides the step-by-step feeding mechanism to be described presently, the lamp is provided with the usual shunt and series coil gear for controlling the arc, and the negative carbon magazine is pivoted for this purpose. Each magazine will hold nine carbons, which are pressed towards the working end by a spring-controlled arm. The arrangement for making contact to each carbon consists of a heavy copper block operated by a weighted lever. The nose of this contact block is driven by the weighted lever along a line at about 45° to the carbon, so that the downward pressure is able to force the block away, and give sufficiently free entrance-way for the oncoming carbon. If the contact block were forced straight at the carbon in a line at right angles to it, it would totally obstruct the new carbon. Although the nose of the contact travels along a path at 45° to the carbon, nevertheless, the general disposition of the contact surface does not alter much, owing to the other end being guided along a slot at a point comparatively far removed from the carbon. By this arrangement the surface presented to the carbon remains the same for all variations in diameter of the carbon, which condition cannot be got with an ordinary pivoted and weighted contact. The carbon-feeding gear consists of a forcing cross-bar which operates small travelling catches engaging with the tops of the carbons. This bar is forced downwards on a rack, step by step, by means of a shunt-feeding solenoid intermittently energised by a make-and-break device. The latter is mechanically controlled by a catch which is part of the arc-regulating device. The negative magazine swings freely, and when this is pulled towards the fixed positive magazine up to a predetermined point, the make-and-break gear is released, and continued feeding goes

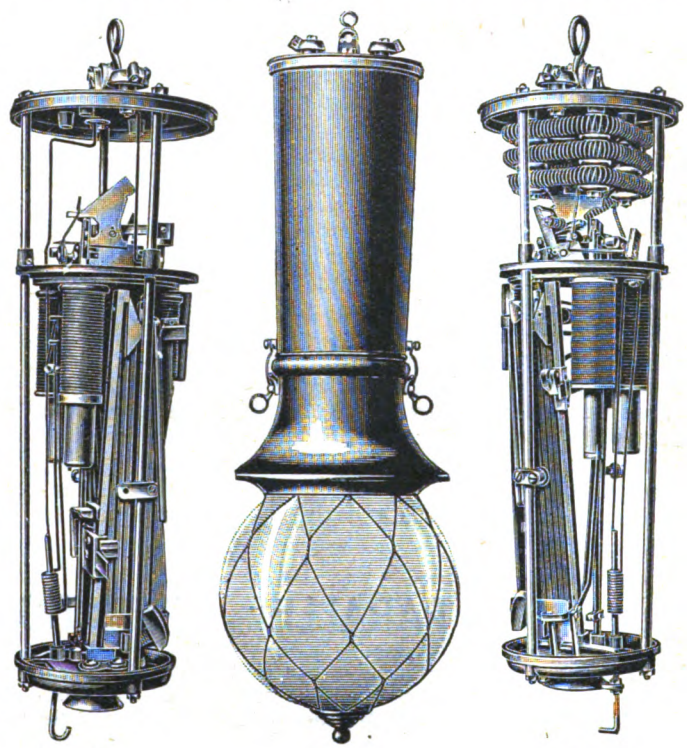

Fig. 1. Fig. 2. Fig. 3.

Interior and Exterior Views of "Angold" Magazine Lamp.

on until the arc is sufficiently shortened to permit of the moving magazine being swung away from the fixed one. By a very simple arrangement the 1½ in. strokes of the feeding solenoid core are converted into ⅛ in. strokes of a saw-toothed rod. This movement is taken up by two double-ended pawls, and transmitted to the cross bar, and thence to the carbons. The bar pushes the pair of carbons downwards at the same speed as they are consumed; and when their ends have been pushed below the magazines, the next two carbons take up their positions immediately behind the burning ends. The pawl gear is then automatically reversed on coming into contact with suitable reversing abutments, and the forcing cross bar is taken step by step to the top of the magazine and the catches travel up the sides of the new carbons. On reaching the top, the pawl gear is again reversed so that the catches engage with the new pair of carbons and begin to force them down. This pushes out the short burning ends as soon as they are sufficiently consumed, and brings the new carbons into action. The raising of the pushing bar to the top of the magazine, a 13 in. vertical movement, is accomplished in less than a minute, during which time the arc burns normally. Generally about a

Digitized by Google

quarter of an hour afterwards, the short stumps are ejected and the arc goes out; but during the short interval while the new carbons are coming into position, an equivalent resistance is thrown into circuit, so that the other lamps in series remain alight. The feeding is continuous during this interval until the new carbons touch, and the light is only extinguished for seven seconds. A very effective arrangement for bringing about the reversal of the two double-ended pawls at top and bottom is provided; the force applied to keep the pawls in operation in the teeth of the rods is maintained right up to the instant of reversal, so that it is impossible for the reversing gear to stand on a dead centre. This steady pressure is brought about by the use of two "V"-shaped parts which engage during the action of reversing, and as one of the pieces is carried on the pawls, the pressure applied to produce reversal is carried through to the pawls themselves, and causes them to press more firmly into the toothed rods. This continues until the points of the two "V"s pass each other, when, of course, reversal is brought about instantaneously.

The make-and-break gear consists of two carbon contacts, and has a quick make-and-break action. The carbons are hammered together at each stroke, and this keeps them perfectly clean, although causing a certain amount of wear. In ordinary use, however, they last two or three years, and then only need to be replenished with the short ends of the best enclosed lamp carbon. Carbon contacts brought together slowly without sufficient force are apt to make bad contact, owing to small pieces of insulating matter which are either contained in the carbon or are carried through by draught into the lamp mechanism. Special attention has been paid in designing the lamp to allow the maximum clearance to all the working parts with a view of maintaining their efficient action even after they have received considerable bending or twisting through rough usage. For instance, the arrangement of the two toothed rods and the pushing cross bar is particularly free, the parts being able to work freely over quite a large range, as the only rigid part is in the line on which the pushing has to be done. Such arrangements considerably facilitate the easy building of the lamp, and a large amount of straining may take place without altering the effectiveness of the mechanism.

With regard to the frequency of the feed, the following figures relating to a 10-ampere lamp are of interest. Each of the nine carbons burns about six hours, so that about every six hours the arc will be extinguished for some seven seconds. Between the top and bottom positions of the pawls on the toothed rods, there are 180 intermediate positions, so that every hour the pawls move down thirty steps. A feed thus takes place about every two minutes. For an 8-ampere lamp, this interval between the feeds will be somewhat longer, say, 2½ minutes. The plunger of the feeding solenoid is practically free, as an instantaneous action is required, but the regulating lever is fitted with an oil dashpot. The positive carbon only is impregnated, but both carbons are cored. An 8 mm. 12-inch carbon is used for the positive, and a 7 mm. for the negative. The interior views in Figs. 1 and 3 show clearly the means for controlling the arc magnetically. This consists of an iron rod projecting down below the level of the arc, on which is wound from 20 to 30 turns of wire in series with the lamp. The magnetic field produced spreads across the arc, and tends to steady it. The actual function of this field and its effect on the regulation of the lamp was the subject of a recent article by Dr. Teichmüller (ELECTRICAL ENGINEERING, January 7th, page 11, and correspondence on the subject in the following issue). The hooked shape of the rod in both the above views has no connection with the magnetic control, but is for the purpose of providing a means of suspending the globe and globe-collar while cleaning. The pressure across the terminals of the lamp is about 42 volts, so that five lamps may be run in series on a 220-volt circuit.

PARALLEL OPERATION OF ALTERNATORS

A PAPER on the above subject was read by Dr. E. Rosenberg, of the British Westinghouse Electric and Manufacturing Co., Ltd., before the Manchester Local Section of the Institution of Electrical Engineers on Tuesday, January 26th, and in London on Thursday last. In introducing his subject, the author states that the question of alternators working in parallel has not come so much to the front in this country as abroad, as the engine makers of this country, by turning to high speeds for both steam and gas engines, had unintentionally kept far from the point where the critical relation between the oscillation of the alternator and the impressed oscillation of the crank began. The phenomenon of hunting in alternators, he continues, occurs mainly when the alternator is subjected to regular impulses occurring at intervals nearly equal to the natural period of oscillation of the alternator, and although cases are on record where the governor of the steam engine caused the dangerous impulses, nearly all can be explained by the regular impulses of the crank mechanism.

The torque diagram of a steam or gas engine can always be represented as a series of waves irregularly formed, but nearly regularly repeated at constant intervals. Considering the time of one revolution as a fundamental period, then it will be found that in all well-balanced steam engines the fundamental wave is only very small. The waves with the biggest amplitude are: In a single-crank engine the second harmonic; in a double-crank engine the fourth harmonic; in a three-crank engine the sixth harmonic. Besides these all other harmonics up to a very high order exist, but as far as the danger of hunting is concerned, the only important fact is that, due to insufficient equality between the impulses on the two sides of a double-acting piston, there is an impulse the period of which is one revolution. If the static balance is not perfect, then the unbalanced weight also gives an impulse with a periodicity of a whole revolution. By perfectly balancing the weights as well as the steam cylinders, the fundamental wave can be reduced to a very small amount, although it will never disappear completely. In slow-speed, two- or three-crank steam engines, where the oscillation of the biggest amplitude lasts a quarter or one-sixth of a revolution, the dangerous amplitude has the duration of one revolution. In multiple four-stroke cycle gas engines with main oscillations of half a revolution or less, the dangerous oscillation has mostly a period of two revolutions. The impulses of ½, ¼, ⅛, &c., revolution are well looked after by the flywheel. They are indeed the main factors that determine the flywheel effect if the flywheel is laid out for any standard cyclic irregularity. When engines of different speeds are running together, equality between the natural oscillating period of the alternator in question with not only the impulses due to her own engine, but also with the impulses of the engines driving the other sets, must be avoided. Let us consider, the author continues, a machine with constant load, and driven by an engine, the torque of which can be represented by a constant torque and a superimposed *oscillating torque* the amplitude of which we will call *M*. The periodicity of this super-imposed torque can be equal to the number of revolutions, or it can be different. This torque gives an oscillating acceleration, inversely proportional to the moment of inertia, which in turn will cause an oscillation of the magnet wheel around the position of the average displacement. The oscillations of the speed will, of course, lag by just a quarter of the period behind the oscillations of the torque. The reaction of the alternator, however, has to be considered, as at the moment of the largest backward displacement, and therefore also at the moment of the largest accelerating force, the machine is supplying less than its normal power to the bus-bars. This variation in output of the alternator, superimposed on the oscillating torque, will act in the same way as an additional oscillating torque would do, and will give an additional oscillating displacement. The amplitude of the oscillating output, super-imposed on the average output, will be proportional to the value of the short-circuit current of the

Digitized by Google

machine and the oscillating displacement, or the angular phase displacement between the alternator and the net. By dividing the figure for the oscillating output by the average angular speed, a value for the corresponding torque is obtained, and we may denote this, the synchronising torque, by M_s. The extent of the final values of the oscillating displacement in comparison with the initial values is determined by the quotient

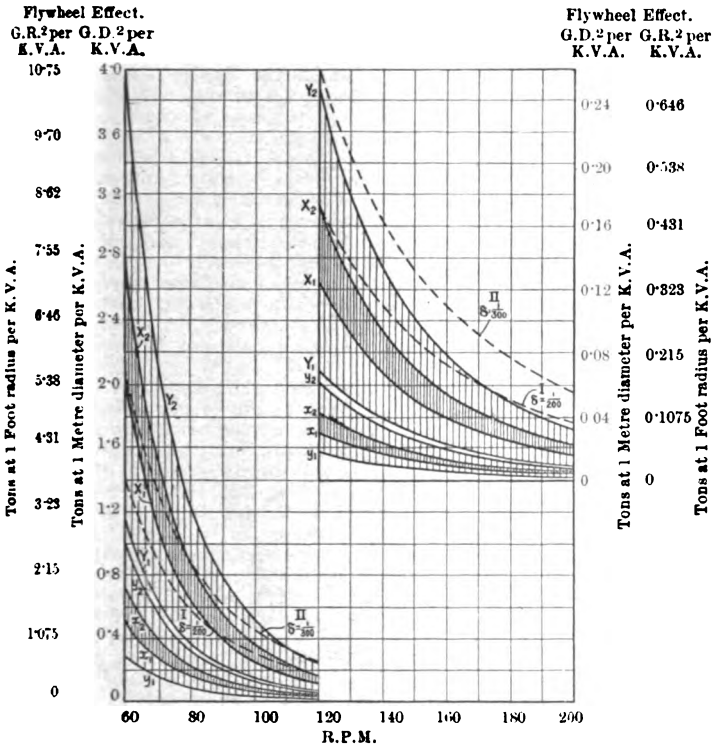

FIG. 1.—CURVES SHOWING VALUES OF FLYWHEEL EFFECT FOR TWO-CRANK CROSS COMPOUND STEAM ENGINES.

of the synchronising torque corresponding to a certain displacement and the oscillating torque which causes this displacement, namely, by the ratio $\frac{M_s}{M}$, which we will call the *reaction quotient*, and denote by q. The final value of the amplitude of the synchronising moment will be equal to $\frac{q}{1-q}M$, and if we know M (the oscillating torque in the original torque diagram) to be a certain percentage of the normal torque, then we can give the final load variation as a percentage of the normal output of the machine by multiplying the first percentage with the factor $\frac{q}{1-q}$, which may be called the *wobble factor*. (An expression for the reaction quotient q, in terms of the machine and flywheel constants, and the derivation of the wobble factor are given in full in the Paper.)

The wobble factor has a finite value if q is smaller than 1. If q is equal to 1, then it would be infinite. That means, for any given primary oscillating torque, the final oscillations would be infinite. In other words, it is a condition of complete resonance. If the wobble factor is plotted as a function of q, curves are obtained which illustrate the well-known theory that in systems without any damping the point of resonance is a point of unsteadiness when the curve disappears into the positive infinite, and for a slight increase of q returns from the negative infinite. In reality, such a point of unsteadiness does not exist, because we have always a third torque which may be called the *damping torque*. The armature of the machine is connected to the net, and we can assume that the flux in it represents a rotating field impressed by the net. If the magnet wheel is not in perfect synchronism with this rotating field, currents will be induced in every closed circuit that represents itself on or near the pole-face, and these currents give a torque like the torque of an induction motor, opposed and proportionate to the oscillating speed. If we provide special damper cages with low resistance, then the current and torque corresponding to a given oscillating speed will be high. If we have only massive pole-shoes, then the higher resistance of the iron will reduce the damping torque for a given oscillating speed, and if we have laminated poles, the action will go deeper and will be visible in the field coils, which in the former cases are protected, as it were, in the electrical shade of the currents in the pole surface. Dampers however, will not reduce mechanical oscillations to any considerable degree, unless the damping torque is nearly equal to the primary oscillating torque. For a small reaction quotient q, the effect of the damper is negligible, but it is the more important the nearer q approaches unity. Thus, for $q=1$ the oscillating speed and the displacement are by no means infinite. The oscillating speed attains such a value that the corresponding damping moment is *exactly* equal to the initial oscillating torque, and this finite oscillating speed, of course, gives also a finite displacement.

Now, if a flywheel is designed for a certain cyclic irregularity, say, 1/200 or 1/300, and we find that for the fundamental wave the reaction quotient is considerably smaller than unity, then it will be sufficient for machines with a small fundamental wave, to consider the critical value for this fundamental wave only, and to see that we are sufficiently apart from it. We call the *critical value* the value of the flywheel effect for which the reaction quotient is unity. In Fig. 1 the critical value of the flywheel per K.V.A. for 50-cycle machines, when the period of the oscillating torque equals one revolution, is plotted as a function of the speed. The short-circuit current will vary according to the excitation of the machine, and, therefore, instead of one curve for the critical value there are two, X_1 and X_2, for values of the short-circuit current of 2·5 and 3·5 times the normal current respectively. The other curves, Y_2 and Y_1, represent the flywheel effect required for reaction quotients of 0·7 and 1·75 respectively. So long as the flywheel effect of the engine under consideration is outside of the danger zone bounded by these curves it will be safe, provided the amplitude of the fundamental wave in the impulse is only a few per cent. of the normal full-load torque. The similar curves x_1, x_2, y_1, and y_2 represent the critical values when the time of one period of oscillating torque equals the time of *half* a revolution (*i.e.*, resonance with the second harmonic), and it will be seen that to avoid the danger zone the flywheel effect must be increased. For speeds above 120 r.p.m. the curves are drawn to a larger scale. For any other frequency or short-circuit current the flywheel effect will be varied in direct proportion. To show how near the usual values lie to the critical value, the curves *I* and *II* are plotted. These represent the average flywheel effect of a two-crank cross-compound steam engine for a cyclic irregularity of 1/200 and 1/300 respectively. Similar curves for a single-crank tandem engine show that a cyclic irregularity of 1/200 would be safe for speeds above 100 r.p.m., and 1/300 would cover the requirements down to about 65 r.p.m. But from Fig. 1 we see that the danger realm for a cross-compound engine for the same cyclic irregularities extends up to 170 and

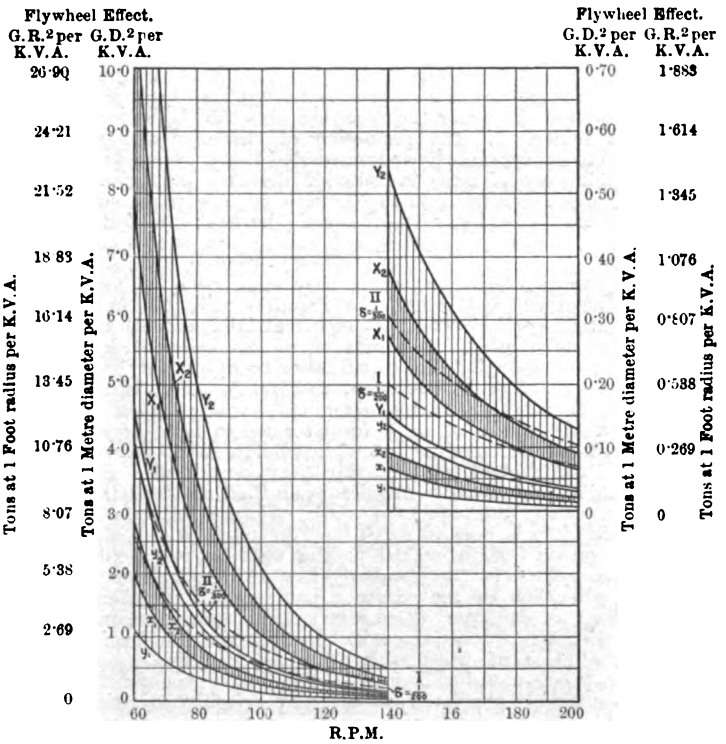

FIG. 2.—CURVES SHOWING VALUES OF FLYWHEEL EFFECT FOR GAS ENGINES HAVING FOUR IMPULSES PER REVOLUTION.

110 r.p.m. respectively, and that is why trouble has been so often experienced in sets of this type.

Digitized by Google

The flywheel effect has been calculated according to the formula—

$$G\,D^2 = \frac{c}{\delta} \cdot \frac{O}{n^3},$$

where G gives the weight in tons, D the diameter of gyration in metres, O output in kilovolt-amperes, δ the cyclic irregularity, and n the number of r.p.m. The constant C has been derived from some specimen engines of recognised makers. In order to get the flywheel effect as tons at 1-ft. radius, the $G\,D^2$ figure is in the $G\,R^2$ scale multiplied by 2·69. Fig. 2 shows exactly similar curves for gas engines with one explosion occurring every half-revolution—for instance, a double-acting, single-crank tandem engine, in which case the time of one period of oscillating torque equals the time of two revolutions. Also the flywheel effect of a three-crank engine with one explosion for one-third of a revolution does not differ much from the values shown in this figure. (Curves for gas engines having one and four impulses per revolution are also given in the paper.)

From these curves it will be seen that for slow-speed engines we must either be prepared to make very heavy flywheels, or we must work between the two danger zones. Gas engines run very much better with a heavier flywheel, but if it is necessary to work between the two danger zones, then we must try and make the danger zones as narrow as possible, and the space between them as large as possible. We can do this by making a close regulation; for example, if the curves are plotted for machines with 3·5 times short-circuit for no-load excitation, and 4·2 times short-circuit current for full-load excitation, then the danger zones are much narrower, and we can avoid them more easily. When working between the danger zones, however, amortisseurs should be employed. For high-speed steam engines of more than 200 r.p.m., it is clear that the standard degrees of cyclic irregularity cover all requirements for alternators of 50 periods and the usual regulation. Three-crank steam engines could, of course, be made with much lighter flywheels, if the makers would design their flywheels taking into consideration only the cyclic irregularity, and then the danger of hunting would not be so remote. But it is interesting to learn that the actual practice of engine-makers is to use for the purpose of stable mechanical running, a considerably higher flywheel effect; for example, the stored energy in the flywheels of Messrs. Williams & Robinson's high-speed engine sets amounts to 2,000 ft.-lb. per I.H.P. for sets which are to be used on lighting and motor loads, and double this energy for traction sets. Comparing such a value with the flywheels necessary for a cyclic irregularity of, say, 1/300, shows that for speeds above 200 r.p.m. the former value is very much in excess of any calculated value.

DISCUSSION IN LONDON.

Mr. G. G. STONEY (Messrs. C. A. Parsons & Co.) said that, of the three factors, uneven turning-moment, flywheel effect, and the reaction of the alternator, he regarded even turning-moment as the most important. The regulation of the alternator was a secondary thing, because alternators carried heavy overloads without dropping out of step, in spite of the fact that with very heavy overloads of from 50 to 100 per cent., as were obtained under certain circumstances, the ratio between the full load current and the short-circuit current was as low as two or even less. There had been difficulty in parallel running with some of the early turbo-alternators, where they used the relay form of "puff" governor, and where the impulses were too few. In several cases, by increasing the number of impulses, the trouble was completely cured. This was most noticeable with high periodicities. Damping coils had also been applied in some cases, but with modern alternators, with fairly thick laminations in the rotors or heavy pole tips, damping coils were not, as a rule, necessary. Difference of wave form seemed to have very little effect upon parallel running, but with complex waves they should not earth the neutral point because very considerable currents of the third and ninth harmonics were then obtained through the star. With alternators of different wave form, working in parallel, it was best to earth the star of only one of them for this reason. With regard to the author's statement concerning governors, he (the speaker) knew of more cases in which a small alteration of the governor put things right than anything else. In one case there was a large turbine running in parallel with a reciprocating engine, and the simple expedient of hanging a piece of wood with a length of string from the governor lever, and immersing the wood in a tin can full of water, completely cured the trouble. By suitably adjusting the damping effect obtained with a dash pot and a sufficiently viscous fluid such as oil or water, the greater part of the trouble could be got over. Great attention should be paid to the adjustment of the governor. High-speed governors with light balls moving at a high speed seemed better for parallel running than heavy, slow-running governors. In one curious case, where they had complaints about parallel running, the difficulty was completely cured by simply damping the ammeters. The ammeters were undamped, and happened to have a period just about the same as that of the oscillations in the system, and the result was most disastrous. In conclusion, he mentioned that he had never failed to run his machines in parallel with anything; but, as a saving clause, he always put in his contracts that he guaranteed to parallel with all the other engines and alternators in the station, provided they would run in parallel with one another. He was happy to say that he had never had to take advantage of this clause.

Mr. F. H. CLOUGH (British Thomson-Houston Co.), speaking with reference to the method of stating the cyclic irregularity, expressed the opinion that this was best specified by stating the maximum displacement of a point on the flywheel from that which it would have with uniform rotation. If the electrical oscillations came within a certain percentage of the impressed oscillations of the engine, there would then be a very great magnification of this initial small displacement, but so long as they did not come near that, there would be no magnification of the initial displacement, and it was then unnecessary to calculate exactly what the displacement was. With regard to dampers, it was difficult to see that they were of very great value, as the flux tended to remain in the centre of the pole, and therefore the actual cutting of these dampers must be small, and consequently also their effect in improving the parallel running. Where they were running gas engines in parallel, however, they could not afford to neglect any means of improving the working.

Mr. G. W. O. HOWE (Central Technical College) said that, for parallel running, the proper setting of the valves, so as to distribute the steam equally on each side of the piston, was most important. His experience was that this was the usual cause of the trouble. He showed an actual turning moment diagram from which he said it was obvious that this was the cause of the trouble, for it was calculated from the diagram that the actual flywheel required under those circumstances would probably have three times the moment of inertia of the flywheel actually fitted to the engine. It was cured by altering the valve settings. He would like to know if Dr. Rosenberg had seen a Paper which was read in 1902 by Mr. Barnes before the American Institute of Electrical Engineers, in which the author suggested the use of small flywheels and amortisseurs, and argued that if they had heavy dampers that was sufficient, and that 25 per cent. or 30 per cent. circulating current was quite immaterial. Dr. Rosenberg's cures seemed to be always more flywheel. Another point was that the author often used the term "cyclic irregularity"; he would like to know how it was arrived at, as it was very difficult to determine. There had been several methods suggested, but most of them seemed rather laborious or inaccurate.

Dr. SILVANUS P. THOMPSON, F.R.S., assured the author that cases of alternators hunting did happen in this country, but that they did not give much trouble, because those who had met with this difficulty had learned how to deal with it. He wished there was a commercial instrument for measuring cyclic irregularity. There were four different things which could be measured: (1) Cyclic irregularity of torque; (2) cyclic irregularity of acceleration (which was the same thing); (3) cyclic irregularity of speed; and (4) cyclic irregularity of position, or what Dr. Rosenberg called the slip by analogy with the induction motor. Cyclic irregularity was not so familiar as it might be, and the values which were assigned were certainly open to considerable question as to their precision. One thing the author had clearly shown was, that they should avoid running alternators with any kind of engine which ran under 100 revs. per minute. If this were translated into poles, with machines intended for a normal frequency of 50 cycles per second, they must not use more than 40 poles. In this country, however, we were much more accustomed to machines with four or six poles rather than machines with 70, 80, 100, or 110 poles, which were common in Continental stations. He was not referring to large machines driven by water power where cyclic irregularity did not count, and where the very slow speeds made it possible to use alternators with a very large number of poles. English experience was certainly in favour of high speeds to free us from this trouble. With regard to amortisseurs, he had never been able to understand why a mere chunk of copper placed between the tips of the poles should satisfactorily act as an amortisseur. To be useful, so far as he could see, it should pass through the poles and not simply round them. Another point brought out by the author was the rather surprising one that, in spite of all cyclic irregularities, it was safer to use single-acting than double-acting engines.

Mr. H. M. SAYERS said that many years ago he had had a practical demonstration showing that trouble with hunting could be avoided to a very large extent by having alternators in which the armatures had small ohmic resistance, and which were good regulating machines. There was not an entire absence of theoretical treatment of this subject in English, and he would like to refer to two Papers by Dr. B. Hopkinson, one before the British Association in 1903, and another before the Royal Society in the same year. Those two Papers gave an extremely lucid account of the whole subject. The effect of governors in producing hunting was not to cause dangerous oscillations, but to throw the load from one machine to the other in accordance with the frequency of the governing oscillations. He had found

Digitized by Google

a very simple cure for that—namely, to run all the machines without governors, except one, and make this govern the speed of the station. The effect of the different characteristics of dynamos running in parallel was well demonstrated in one station with which he had been connected. There were nine machines of similar size and output, and the engines were identical. Six of the alternators were of an early type, and the remaining three of a later type. The latter were much worse regulating machines than the earlier ones, having a good deal less material in them, shorter air gaps, and requiring much larger excitation variation between no load and full load. These three machines would not run in parallel together, but the earlier machines ran in parallel very well; the bad machines would also run in parallel fairly well with the good ones. In the same station there was another type of engine running at a higher speed, coupled to another type of alternator. This was a very much better regulated machine, and he found he could reduce any of the machines to comparatively good behaviour if he ran them in parallel with this particular machine. Indeed, this one excellently regulating machine would keep in order five or six badly regulating machines, which would not run in parallel together without it.

THE PRESIDENT (Mr. W. M. Mordey) said that exactly forty years ago the first Paper on parallel working of alternators was read by their honorary member, Mr. Henry Wilde, and was published in the *Philosophical Magazine* for January, 1869. They should also not forget the work of the late Prof. John Hopkinson and Prof. Adams, who, in 1882, not knowing of Wilde's work, gave a mathematical demonstration of parallel working, and followed it up by an actual demonstration with the old magneto alternators now in the St. Catherine's lighthouse. He would like the author to say something about the effect of flexible couplings in the driving of alternators. The very best example of parallel working he had seen was with some 150 kw. Westinghouse gas-engine sets, which were coupled flexibly, the driving being through a spring giving freedom of motion both ways, so that any irregularities in the drive could be taken up. He would like to know how the variation of turning-moment was measured. No doubt it was more often calculated, but it ought not to be difficult to make an apparatus for this purpose. He had realised that, in order to obtain successful parallel running, it was absolutely necessary that there should be no transformer action between the armature and the field magnets. If alternating currents were induced in the field circuit they could be damped out by the insertion of a choking coil.

Dr. ROSENBERG, in replying to the discussion, said that, in general, cyclic irregularity was not measured, but was calculated from the turning moment diagram and represented the difference between the maximum and minimum speed compared with the mean speed. Attempts to measure this had been unsuccessful, because changes due to variations in the admission of steam or the load on the engines, caused bigger irregularity than the cyclic irregularity during one revolution. With regard to Mr. Clough's remark about specifying the displacement, many American and Continental firms followed this, prescribing that the displacement of the flywheel should not exceed a certain limit, often given as three degrees. This would be all right if it were the final displacement, *i.e.*, the initial displacement magnified by the electrical reaction, but an initial displacement of three degrees would not do. Mr. Howe had mentioned that the Paper repeatedly recommended more flywheel. It was so because it was the best for the particular examples mentioned. Mr. Clough rather misunderstood the Paper on the question of the damper. This, in many cases, was of no value whatever, whilst in others it helped enormously. He did not think they need come to the conclusion mentioned by Dr. Thompson, that no alternator should be used with more than 40 poles, as if the conditions were calculated out properly they could run to 60 or even 100 poles.

DISCUSSION IN MANCHESTER.

Mr. S. J. WATSON (Bury Corporation Electrical Engineer), who was in the chair, said that when alternators coupled to engines of different types were run in parallel, there was nearly always trouble, but that if the engines were all of the same pattern the alternators would parallel well, even if they were driven by slow-speed gas engines. The best type of engine for parallel running was undoubtedly the turbine, and the high-speed multiple crank tandem engine came second.

Mr. J. S. PECK (British Westinghouse Co.) did not agree with what Mr. Watson said about engines of the same size and make always operating in parallel satisfactorily, because he knew of a few cases where both engines and generators were made by the same manufacturers at the same time, to the same specifications, and yet there was the greatest difficulty experienced in getting satisfactory parallel operation.

Mr. R. PORTER pointed out that it appeared from the curves that double-acting tandem gas engines were likely to give trouble if the flywheels were designed only from a mechanical point of view. He had seen a great number of installations of this type driving alternators in parallel with absolutely no trouble, but had only noticed in one instance the use of special damping devices. This instance was the Milwaukee Northern Railway Co., U.S.A., where twin-tandem double-acting 2,000-h.p. sets were in use. The single-phase generators in this case had solid steel poles, and a brass ring on each side of the rotor fixed to the pole pieces by brass screws. Usually the only specification that the gas-engine maker received was that the flywheel effect should be sufficient to ensure a cyclic irregularity not exceeding 1 in, say, 250. This was caculated graphically from the engine curves, and a good margin of safety added to allow for possible misfires, &c.

Mr. A. E. MCKENZIE related an instance of hunting with three 400 K.V.A. (single crank) sets. Any one of these three sets would run with the other two, but no two out of the three would run together. Synchronising the cranks and varying the angles of the cranks had no effect, but eventually the whole trouble was cured by putting copper damping rings round the pole pieces. In the same station were some motor-alternators made by Messrs. Brown Boveri, which would run well with any of the other sets, but not in parallel with each other. Eventually that trouble was overcome by shaping off the edges of the poles, thus making the air-gap between the pole pieces greater.

Mr. C. C. AITCHISON thought that most of the troubles in parallel running had been with frequencies of 100 cycles. In certain cases which he knew of amortiseurs had been applied successfully.

Mr. M. HARTENHEIM (British Westinghouse Co.) referred to a case in which some old generators, the wave-form of which differed widely from the ordinary sine wave, refused to run in parallel with modern generators with sinusoidal E.M.F. curve. The trouble was overcome by altering the shape of the pole tips of the old machines. It was clear that differences in the instantaneous values of the E.M.F. curves produced heavy cross currents between the machines, and these might have unfavourably affected the parallel running of the said generators.

Mr. J. H. THOMAS, dealing with the question of flywheel effect, mentioned a case of an alternator of 1,600 kw. output, driven by a Nurnberg gas engine (twin-tandem arrangement) of 2,400 h.p. and running at 94 r.p.m. The flywheel inductor of the alternator weighed about 76 tons. He thought that it was very general for manufacturers, if they did not fit dampers in the first instance, at least to make arrangements at the pole pieces, so that they could be fitted afterwards in case of trouble.

Mr. T. H. SWINBURNE said that in the case of a separately excited plant, it would seem that any variation in prime mover, or in the exciter itself, would not necessarily affect all the alternators in quite the same manner. Trouble also arose when one alternator excited from a series-wound exciter was run in parallel with another excited from a shunt machine.

Mr. MILES WALKER (British Westinghouse Co.), in a written communication, commended the author on the excellence of his Paper, and enlarged on the complexity of the subject. The matter was so difficult to predetermine, he said, that engineers generally put on a heavy flywheel and trusted to luck. He suggested that the symbols used in the Paper might have been better chosen, and asked for an exact definition of the term "net vector." Did it correspond with the bus-bar voltage? did it have a constant speed? and if so, how could I_0 multiplied by σ (the angular displacement between the machine and the net vectors) represent the synchronising current and be independent of the self-induction of other machines?

Mr. ROSENBERG, in reply to Mr. Walker, defined the "net vector" as the vector of a synchronous machine replacing the net and taking at every moment the same current as the net would take. In the case of a lighting load, or an induction-motor load, the net vector lagged by a fixed angle behind the bus-bar vector. Mr. Walker was quite right in pointing out that in many cases the net vector would not rotate with constant speed, but might have an additional oscillating movement; that did not affect the calculations; it meant only that we had still another component of the synchronising torque with another frequency. As with the other components of the oscillating torque, this would be treated on its own merits, and the value of the reaction quotient "q" for this given frequency would be determined. Mr. Watson's remark as to the adaptability of three-crank engines for parallel operation was quite right as far as high-speed engines are concerned, fitted for mechanical reasons with a good substantial flywheel. But for machines of this type of moderate speed fitted with a flywheel just sufficient for a cyclic irregularity of 1 to 200, or 1 to 300, the results would be different. In reply to Mr. Porter, damping arrangements in generators driven by single-acting gas engines with one explosion per revolution were not necessary, and gave no advantage in 50-cycle machines of the standard regulation and speeds of 100 r.p.m. or more. The instance of hunting mentioned by Mr. McKenzie was hardly to be ascribed to the crank mechanism, as in engines of that speed the flywheel effect was, as a rule, sufficiently above the critical value; but it might be that the engine governors were responsible for the hunting. Mr. Hartenheim had mentioned the influence of the wave-form of E.M.F., but this wave-form difference only gave rise to wattless current of higher frequency, and not to a fluctuation of power. If in certain cases a change in the pole tips of an alternator affected the hunting, then it was not due to the change in wave-form, but to the change of the short-circuit current connected with changing the pole arc. This was equivalent to an alteration of the air-gap. As to Mr. Swinburne's question, the author did not see that it made any difference to parallel operation whether the exciters were series or shunt wound.

LOCAL NOTES

ABERDEEN: *Proposed Electrical Exhibition.*—A Sub-Committee of the Electricity Committee, which has in hand the promotion of an electrical exhibition, met a number of local electrical traders last week with a view to co-operation in the matter. The latter, however, expressed the emphatic opinion that, whilst the price of electricity in Aberdeen remained at the present high rate, electricity could never compete with gas, either for heating or power purposes. The impression given was that, under existing conditions, the local electrical traders think it useless to promote an exhibition, and will give no assistance.

BIRMINGHAM: *Electric Supply Tariff.*—The charges for lighting and power are to be reduced as from the March quarter.

BISPHAM: *Electric Lighting.*—The Blackpool & Fleetwood Tramroad Co. is to be asked the terms upon which a supply of electricity can be given under the Council's Provisional Order.

CARDIFF: *Condition of Tramway Track.*—The City Engineer (Mr. Harpur) and the Electrical Engineer (Mr. A. Ellis) have presented a report dealing with the tramway track. This states that the tracks in Cardiff, considering the time they had been down, namely, six to eight years, had stood equally as well as most tracks in the kingdom, and very much better than many. Any defects now apparent were not due to inferior materials or workmanship in the construction of the lines, but were inevitable in the running of a tramway system where the street traffic was heavy and the service so frequent as in Cardiff. Two particular forms of trouble had been experienced which were the cause of the greatest difficulty. Those were rail corrugations and hammered joints. As to the causes of rail corrugation, no solution had yet been arrived at. A special cause of wear on the track generally was the serious heavy traction engine and steam locomotive traffic upon the streets, which were extremely destructive, not only to the tramway, but to all and every form of road construction. For instance, in Adam Street, where the roadway was very wide, and there was ample room for all kinds of traffic, the tramway track was used and worn by the heavy lorries owned by the Great Western Railway Co. and their contractors, which seemed to prefer the tramway track to the macadam roadway. Special arrangements were at present being made to put into operation immediately a system of regularly scrubbing the rails with tools provided for the purpose and so keeping corrugations down and consequently the shattering of the foundations through vibration. In Glasgow it was said that corrugations cost the City Council from £10,000 to £15,000 per annum. The cost of putting the Cardiff track into good condition at the present moment was estimated as follows:—Plating 300 flattened rail joints at £2, £600; 5,300 anchors at 35s. each, including taking up and replacing wood paving where loose, £9,275; 2,600 superficial yards, new paving at 10s. per yard, £1,300; total, £11,175. The report has been referred to the Tramway Committee.

DARLINGTON: *Tram Fares.*—The Corporation has decided to re-introduce the system of halfpenny fares as from April 1st.

DUBLIN: *The Bellis-G.E.C. Set.*—The report of the Lighting Committee on the long-standing disputed account of the General Electric Co. announces that a settlement can be arrived at on the following terms:—(1) The Corporation and the Company to turn back to back on the claim of £1,460 and the reduced counter-claim of £1,381. (2) The Company to guarantee to replace the entire alternator of the turbine set by another of a make approved by the City Electrical Engineer, if it should be proved at any time within two years from the date of the official test that the working of the turbine on the circuit is found impossible owing to defective regulation; and (3) To cover this and the other deficiencies mentioned in connection with the Bellis Morcom set, the General Electric Company to pay to the Corporation the sum of £300.

DUDLEY: *Insurance of Plant.*—The Council has decided to insure, provisionally, for £10,000 the cars and depôt purchased from the tramway companies.

DUMFRIES: *Infirmary Electrical Equipment.*—At the annual meeting of the Governors of the Dumfriesshire and Galloway Royal Infirmary on Friday, it was stated than an X-ray apparatus had been presented to the institution, and that arrangements are being made for the installation of electric lighting.

EDINBURGH: *Power Supply.*—A conference is being convened by the Corporation, of authorities in Scotland owning electricity works, in respect of the scheme of the North British Electrical Power Syndicate, Ltd., which proposes to supply electricity along the route of the Scottish railways, and to enter into agreements with the railway companies for way-leaves in connection with its mains. This matter was raised at the meeting last year of the Incorporated Municipal Electrical Association, and the strongest opposition is to be offered to it.

GLASGOW: *Postmaster-General and Tramway Poles.*—The Postmaster-General has exercised his statutory powers to attach telegraph wires to the tramway poles so far as the suburban parts of Glasgow are concerned. The Corporation are asking for the highest rate of remuneration for the use of the poles which the scale admits.

HESSLE: *Electric Supply.*—A report has been submitted to the Hull Electricity Lighting Committee with reference to the supply of electrical energy in Hessle. In order to carry out the scheme effectively it is pointed out that the Hessle provisional order should be acquired by Hull. The estimated capital cost of the scheme is £15,000, and that there will be a loss of £561 upon the first few years' working. There should be a small profit after.

HYTHE: *Tramways Bill.*—The Council has decided to petition against the Bill of the National Electric Construction Co., which asks for powers to instal the overhead system of electric traction instead of a surface-contact system, as originally agreed upon.

ILFORD: *Tramway Management.*—Mr. A. H. Shaw, who has for some time been acting as electrical engineer and tramways manager, has resigned that latter appointment. Mr. Shaw will continue as electrical engineer, his salary being reduced by £100 per annum. A tramways manager is to be appointed.

LIVERPOOL: *The Electricity and Tramway Undertakings.*—An increase in the rates for the current year is announced of 6d. in the £. Among the reasons advanced for this addition is that the contribution from the tramways undertaking, owing to trade depression last year, was reduced from £28,000 to £25,000, and from the electric supply undertaking from £27,500 to £20,000.

LONDON. *London County Council: Tramways.*—The proposal to extend the King's Cross-Farringdon Road tramway to Charterhouse Street, near Holborn Viaduct is meeting with strenuous opposition from the holders of the notorious costermongers' stalls along Farringdon Road, as the existence of a tramway down that thoroughfare would mean their exclusion.

Subject to the Bermondsey, Deptford, and Greenwich Councils giving their consent to the electrification of the London, Deptford, and Greenwich tramways, and to bear one-third of the net cost of the necessary street widenings, the London County Council has intimated its willingness to apply to Parliament for the necessary powers. The Bermondsey Council is not inclined to agree, except on the understanding that they bear no portion of the cost of street widenings.

The Government authorities have agreed to setting back the boundary-wall of Woolwich Dockyard in order to permit the laying of a double line of tramways between East Greenwich and Beresford Square, Woolwich. The cost is estimated at £9,000, of which two-thirds will be borne by the London County Council and one-third by the Woolwich Borough Council.

Fulham: Electric Lighting.—The Electricity Committee have decided to waive the minimum charge of £1 per annum which is made for heating and motive-power purposes, as this charge appears to create dissatisfaction amongst small consumers.

Hammersmith: Tramways.—The Law and Parliamentary Committee recommend that a petition be lodged against the Bill of the London United Tramways Co, Ltd., which contains provisions postponing the purchase period of the company's tramways in Hammersmith, and others relating to mutual running power over the lines of the company and the London County Council. At present the company can be given six months notice on July 1st of this year, or within six months thereafter, or within six months after the expiration of every subsequent seven years.

MANCHESTER: *Overhead Wires.*—The Watch Committee recommends that if the "Gamewell" fire-alarm system be adopted, the use of overhead wires should be prohibited. Sir Robert Hunter, solicitor to the General Post Office, has written with regard to certain proposed overhead telegraphic lines in various streets of the city, pointing out that, as underground lines are not nearly so efficient as overhead lines, and as many of the wires will be used for trunk telephonic speaking, the Postmaster-General will be bound to press for an overhead line.

MORECAMBE: *Tramways Purchase.*—The arbitrator's award with regard to the purchase of the horse tramway system by the Corporation has been issued. The purchase price is fixed at £13,391, plus the costs of the arbitration. This amount is about £5,000 less than the company's estimate and £2,000 greater than the Corporation's estimate.

RHONDDA: *Electric Supply.*—The Penygraig Chamber of Trade have approached the Porth Chamber of Trade with a view to a joint request to the Rhondda Tramway Co., Ltd., to apply for powers to provide electric light and power in the Rhonddas.

SALFORD: *Electricity Committee.*—Councillor W. H. Barrett has resigned his position as Chairman of the Electricity Committee. The *Manchester Guardian* states that the step will be regretted by all who are acquainted with Councillor Barrett's work in connection with the undertaking, and though it is probable that an effort will be made to induce him to reconsider his decision, there is some doubt as to whether it will prove successful. There are internal differences in the committee, and for some time past it has been entering into what

Digitized by Google

are termed "secret contracts" of supplying current in particular cases at less than cost price. It was partly in consequence of this that a special committee was appointed a week or two ago to consider and report on the desirability of publishing the prices of all contracts. This committee has not yet, however, furnished its report. Two other members of the Electricity Committee have since resigned.

Electricity Supply.—The Electricity Committee have decided that Wilburn Street depot is the best available site for the proposed new generating station. They further consider that the offer of the Lighting and Cleansing Committee to transfer the site for £25,000 is reasonable.

SHEFFIELD: *The Trackless Trolley System.*—Councillor Fenton, Councillor Bailey, and the tramways manager, Mr. A. R. Fearnley, have left for Vienna to inspect the trackless trolley system which is in use on the Continent.

SUNDERLAND: *Electricity Output.*—During the half-year to December 31st, the units sold by the Corporation electricity department have fallen short by 1,100,000 of the estimate put forward in June.

WEST HAM: *Suggestion for an "Eastminster."*—The third annual dinner of the staff of the West Ham electricity department was held on Thursday. The most noteworthy feature of the proceedings was a suggestion by the Mayor of West Ham (Alderman H. W. Littler, J.P.) that West Ham, East Ham, Leyton, Walthamstow, Woodford, and Wanstead (all of which are in the same Poor Law Union), and Barking, Dagenham, Ilford, and the portion of Kent north of the Thames known as North Woolwich, should be amalgamated to form a City of Eastminster. As supporting this argument, Alderman Littler instanced the recent Potteries' federation scheme.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ALGERIA.—The Chamber of Commerce of Bona intends, says the *Board of Trade Journal*, to supply the quays of the port with electric power and light. The concession for the works includes a subvention of 100,000 francs if a sufficient reduction is made in the sale price to the Council of motive power. Tenders by February 15th, to the President of the Bona Chamber of Commerce.

BELFAST.—As the result of negotiations between the representatives of the Harbour Board and the Corporation Electricity Department with regard to a supply of electrical energy, the former have advised that separate plant should be installed at an estimated cost of £12,000. The Harbour Board, however, after a lengthy discussion, appointed a committee to reopen the matter with the Corporation.

CLACTON.—An overhead travelling crane is required for the Council's generating station. Particulars from the Electrical Engineer (fee one guinea, returnable), and tenders to the Clerk by February 17th.

DUNDEE.—Tenders are invited for a high-tension feeder panel in a static transformer sub-station. Particulars from the Electrical Engineer, and tenders by February 8th.

KENDAL.—A scheme for the erection of an electricity works, at an estimated cost of £10,000, is under consideration.

LONDON: *Southwark.*—The Finance Committee of the London County Council recommend sanction to a loan of £8,500 for electricity extensions as follows:—Mains extensions £4,586, repayable in 30 years; plant, &c., £1,525, 20 years; house services, £1,313, 12 years; and meters, £1,076, 10 years.

Westminster.—The Westminster Electric Supply Corporation, Ltd., invite tenders for high- and low-tension switchboards, and low-tension switchboard and battery boosters. (See an advertisement this week.)

MAIDENHEAD.—Distributing mains to the estimated value of £900 are to be purchased, and an application is to be made to the Local Government Board for sanction to borrow £2,000 for electricity works extensions.

MORLEY.—A Local Government Board inquiry has been held into an application by the Corporation for sanction to borrow £11,759 for the purposes of the electricity undertaking. Of this sum £2,317 is excess expenditure over previous loans. The remainder is mainly required for plant to meet the additional tramway load consequent upon the construction of the new tramways connecting up with Leeds.

REIGATE.—A Local Government Board inquiry has been held into an application by the Corporation to borrow £4,000 for the purposes of the electricity undertaking. The inquiry was closed, but considerable information is to be forwarded to the Board concerning mains, capital expenditure, number of consumers, &c. Of the loan asked for, £1,600 represents excess expenditure.

SHEFFIELD.—The Electric Light Committee require steam and feed piping, valves and connections, water meter and sundry ironwork for the new boiler at the Neepsend power station. Particulars from the Electrical Engineer (fee £1, returnable), and tenders by February 15th.

SOUTH AFRICA.—The Johannesburg Lighting Committee recommends an expenditure of £3,300 on mains.

WEDNESBURY.—Some time ago the Town Council obtained the consent of the Local Government Board to a loan of £800 for the purpose of using the tramway poles for carrying overhead feeders intended to supply the district of King's Hill with electric current. The tramways company now refuse to permit the Council to use the tramway poles, except on the payment of £380 and various indemnities. In the circumstances the committee have decided to recommend that the wires be laid underground, and that a further application be made for sanction to borrow £1,700 for the purpose.

WISHAW.—Tenders are invited for the supply of carbons during the coming year for Oriflamme arc lamps. Forms, &c., from the Electrical Engineer.

Miscellaneous

AUSTRALIA.—The Board of Trade correspondent at Melbourne (Mr. M. Hirsch) has forwarded a copy of the specification and conditions for the supply of (*a*) 5,000 telephone cases and associated parts, and (*b*) telephone parts for 5,000 telephone wall sets, tenders for which will be received by the Secretary, Postmaster-General's Department, Melbourne, up to 3 p.m. on February 23rd. Offers will be considered for any quantity of sets from 1,000 upwards. Preference, says the *Board of Trade Journal*, will be given to Australian material. The conditions and specification may be seen by British firms on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

The same exchange states that tenders by the Commonwealth Postmaster-General's Department for the supply of telephone material are notified, the times given being the latest up to which tenders will be received:—March 23rd.—Office of the Deputy Postmaster-General, Melbourne: Supply, delivery, and erection of power plant for the Central Telephone Exchange, Melbourne. March 29th.—Office of the Deputy Postmaster-General, Brisbane: Supply and delivery of ironwork, insulators, iron wire, bronze wire, and covered wire. May 19th.—Office of the Deputy Postmaster-General, Sydney: Supply and delivery of two multiple magneto switchboards. Tender forms may be obtained and preliminary deposits paid at the Commonwealth Offices in London, 72 Victoria Street, S.W.

BLACKPOOL.—The sum of £300 is to be spent on electric heating and cooking apparatus, which will be let out on hire.

CANADA.—Considerable extensions of the telephone system are contemplated.

ILFORD.—Tenders are invited for electrical stores, including meters, cables, incandescent lamps, arc lamp carbons, house-service fuse-boxes, and joint boxes. Particulars from the Electrical Engineer, and tenders to the Town Clerk by February 23rd.

LEEDS.—Tenders are invited for stores for the Electric Lighting Department during the year ending March 31st, 1910. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 25th.

LONDON: *Hampstead.*—The Borough Council are to fix underfeed stokers to the eight boilers in the north boiler-house at the electric lighting station at a cost of £2,050. The provision of these stokers will, it is thought, result in a saving of £1,700 a year, as they will make it possible to use slack instead of Welsh coal.

Paddington.—Tenders are invited for stores, including electric lamps and shades. Particulars from the Borough Accountant, and tenders to the Town Clerk by February 13th.

NEWPORT (MON.).—Tenders are invited for three complete double-deck tramcars. (See an advertisement this week.)

PORTSMOUTH.—Tenders are invited for the supply of stores to the Tramways Department during the year ended March 31st, 1910. Particulars from the Tramways Manager, and tenders by February 15th.

SALFORD.—Tenders are invited for stores. (See an advertisement this week.)

SOUTH AFRICA.—Estimates are being inquired for for the installation of 97 electric motors in the pits of the Rand Mines, Ltd. The mechanical engineering department of Messrs. H. Eckstein & Co. have the matter in hand. The motors aggregate 8,015 h.p. and vary from 25 h.p. to 180 h.p.

STOCKTON-ON-TEES.—Tenders are invited by the Electricity Committee for stores during the year ending March 31st, 1910. Particulars from the Electrical Engineer, and tenders to the Town Clerk by February 15th.

WORTHING.—Two additional feeder cables are to be laid, at an approximate cost of £1,600. Application is to be made for a loan of £3,900 for prospective requirements for meters, house services, and distributing mains during the next two years.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Tenders are invited for the electric wiring and fitting of Redman's Road elementary school, Stepney. Particulars

Digitized by Google

from the Engineer to the Council, Mr. Maurice Fitzmaurice, and tenders to the Clerk by February 17th.

E.—School, Buxton Street, Whitechapel (£11,723). Builders, C. P. Roberts & Co., 138 St. Paul's Road, Highbury, N.

N.—County school (£13,493), Southgate. Builders, Mattock Bros., Winkfield Road, Wood Green.

School, Barnsbury Park (500 places), Islington. Architect, T. J. Bailey, L.C.C.

N.W.—Additions to Grammar School, Kilburn. Builders, W. Lawrence & Son, Moselle Works, Tottenham, N.

S.W.—Training college (264 places); two hostels (100 places); secondary school (456 places), all at Furzedown, Wandsworth. T. J. Bailey, Architect, L.C.C. Education Committee, Victoria Embankment.

School, Hitherfield Road, Wandsworth (£10,117). Builder, Galbraith Bros., Ltd., 46 Camberwell Green, S.E.

W.—Schools, Camden Street and Torriana Avenue, St. Pancras. Architect, T. J. Bailey, L.C.C.

PROVINCES.

ALDERSHOT.—Hippodrome. Architect, Bertie Crewe, 75 Shaftesbury Avenue, W.C.

ALNWICK (Northumberland).—Additions to Lloyd's Bank. Architect, G. Reavell, jun., Bondgate, Alnwick.

BANGOR.—Sanatorium (£3,000). Architect, H. J. Blanc, Rutland Square, Edinburgh.

BIRMINGHAM.—Skating rink. Architect, J. Archer, 13 Temple Row, Birmingham.

BRISTOL.—The question of the substitution of electricity for gas by the Bristol Education Committee is now under consideration.

The Corporation Electricity Committee invite tenders for the third instalment of the wiring of the Avonbank electric lighting station. Particulars from Mr. H. Faraday Proctor, City Electrical Engineer, and tenders by February 11th.

CATERHAM (Surrey).—Additional infirmary accommodation at Asylum. W. T. Hatch, Engineer, Metropolitan Asylums Board, Victoria Embankment.

CHESTER.—Hippodrome (3,000 places). Architect, W. T. Lockwood, 88 Foregate Street, Chester.

DARLASTON (Staffs).—School (£1,059). G. Balfour, Secretary, Stafford Education Committee, Stafford.

DUMFRIES.—Electric light is to be installed at the Dumfriesshire and Galloway Royal Infirmary.

DUNDEE.—Baths. Architect, H. Thomson, 87 Commercial Street, Dundee.

HORSHAM.—New Congregational Church (£3,000), also proposed Sunday school, &c. (£1,500). Rev. Herbert J. Crouch, minister.

MERTHYR.—Conversion of Cyfarthfa Castle to secondary school. T. F. Harvey, Borough Surveyor, Merthyr.

MORLEY.—Alterations and additions to Peel Street Mills. Architect, T. A. Buttery, Queen Street, Morley.

OSWESTRY.—Sunday school. Architect, W. J. Oliver, 1 Darlington Street, Wolverhampton.

OXFORD.—School. City Surveyor, Oxford.

Wing, Oriel College. Architect, Basil Champneys, 19 Buckingham Street, Strand.

PRESTON.—Extension of County Offices (£20,000). H. E. Clare, Clerk, County Council.

PONTYPRIDD.—The Electric Light and Tramways Department invite tenders for the supply and delivery of installation fittings, lamps, and sundries. Particulars from the Electrical Engineer, and tenders to the Town Clerk by February 22nd.

PRESTWICK.—Tenders are invited for the electric wiring of the Clough Sewage Works. Particulars from the Surveyor, and tenders to the Clerk by February 6th.

ROMFORD.—High School for Girls (£8,400). Architects, J. H. Hickton and H. E. Farmer, County Chambers, Birmingham.

RUGBY.—Opera House. Builders, Foster & Dicksee, Rugby.

TENDERS RECEIVED AND ACCEPTED

ACCRINGTON.—The Council has accepted the tender of Messrs. Ferranti, Ltd., for a switch panel.

BLACKPOOL.—Messrs. Howe & Co., electrical engineers, of Blackburn and Blackpool, have received a contract to equip the new Theatre Royal with electric fittings, &c.

BRIGHTON.—The Electricity Committee recommend the acceptance of an offer by Messrs. Babcock & Wilcox, Ltd., to carry out extensions at the Southwick electricity works at £15,370.

CHESTER.—The tender of Messrs. McLellan Bros., of Chester, has been accepted for the erection of a battery-room at the electricity works at £1,880.

DOVER.—A contract has been entered into with Messrs. W. T. Glover & Co., Ltd., for the supply of cables at a cost of £500.

DUDLEY.—The Council have placed an order with the Electrical Co., Ltd., at £48, for the supply of 25 electric meters.

FALKIRK.—An order for 232 cells and an "Entz" booster for working across the outers of the lighting system has been placed with the Chloride Electrical Storage Co., Ltd.

GLASGOW.—The Corporation has accepted the following tenders in connection with the tramways:—Lorain Steel Company, special trackwork; W. C. Yuille & Co., Alfred Wiseman, armature pinions.

LEYTON.—The Council has received the following tenders for electric light installation at Cobbold Road School:—W. G. Cannon & Sons, Ltd. (*a*) with "Simplex" steel conduits, £221 11s., (*b*) with wood castings, £209 10s. 6d.; J. T. Halsey (*a*) £119 16s. 8d., (*b*) £113 19s. 6d.; Headland & Headland (*a*) £155, (*b*) £160; Pemberton, Arber & Carey (*a*) £155 12s., (*b*) £140 14s.; Pinching & Walton (accepted for *a*) (*a*) £109 5s., (*b*) £121 5s.; Ryan & Sons (*a*) £124 10s., (*b*) £123; William Simmons (*a*) £169 19s., (*b*) £160 10s.; Tilley Bros. (*a*) £144, (*b*) £132 10s.; W. R. Woodward (*a*) £117 5s., (*b*) £119 10s.

LONDON: *London County Council.*—The following tenders have been received for the electric wiring of the fire-station in course of erection in Copenhagen Street, Caledonian Road:—Lund Bros. & Co. (accepted), £126 6s.; G. E. Taylor & Co., £135 11s. 11d.; Tilley Bros., £142 7s.; Tredegar & Co., £165 10s.; Comyn Ching & Co., £171; W. Leonard & Co., £250. The engineer's estimate of the cost of the work was £185.

The following tenders have been received for the manufacture, supply, and delivery of 155,000 stoneware cable ducts required in connection with the electrification of certain further sections of the Council's tramways:—Stanley Bros. (accepted), £1,688 15s. (less 2½ per cent. for cash monthly); Hosea Tugby & Co., Ltd., £1,688 2s. 1d.; H. R. Mansfield, £1,688 2s. 1d.; Robinson & Dowler, £1,688 15s.; Doulton & Co., Ltd., £1,723 12s. 6d.; Geo. Skey & Co., Ltd., £1,727 10s.; Sutton & Co., £1,758 10s.; Ensor & Co., Ltd., £1,785 12s. 6d.; James Oakes & Co., £1,824 7s. 6d.; Thomas Wragg & Sons, Ltd., £1,882 10s.; Donington Sanitary Pipe & Firebrick Co., Ltd., £2,037 10s.; Leeds Fireclay Co., Ltd. (50,000), £850 (less 2½ per cent. for cash monthly); Ralph Ashworth & Co. (50,000), £900; A. McNair & Co., £2,925 10s. 5d.; National Fireproofing Co., £2,967 10s. The estimate of the chief officer of tramways, comparable with the above figures, was £1,930.

The following tenders have been received for the supply of screwing machines required for use at the tramway central car repair depot:—Selig, Sonnenthal & Co., Ltd., £250; Schuchardt & Schutte (accepted), £254; Buck & Hickman, Ltd., £316; A. Herbert, Ltd. (alternative tenders), £351, £370 10s.; J. Holroyd & Co., Ltd., £410 10s. The estimate of the chief officer of tramways was £290.

Tenders have been invited from five selected firms for the supply of oil and waste saving machinery required for use at the central car repair depot, but only one tender—namely, that of the Oil & Waste Saving Machine Co., Ltd., amounting to £209 0s. 6d.—has been received. The estimate of the chief officer of tramways comparable with this was £180. A similar machine is now in use at the Greenwich electricity generating station, and it is recommended that this tender should be accepted.

The Highways Committee recommend that the seal of the Council be affixed to an agreement with Messrs. Dick, Kerr & Co., Ltd., to re-wind the 500-kw. motor generator at the Greenwich generating station for the sum of £422.

The following tenders have been received for the laying of stoneware ducts, repaving, &c., in connection with the electrification of certain further sections of the Council's tramways:—Reid Bros. (accepted), £13,356 7s. 8d.; the Westminster Construction Co., Ltd., £13,816 1s. 11d.; Dick, Kerr & Co., Ltd., £13,937 10s. 8d.; W. Muirhead & Co., £15,204 8s. 3d.; J. A. Ewart, £15,260 18s. 10d.; Clift Ford, £16,023; John Mowlem & Co., Ltd., £16,352; British Insulated & Helsby Cables, Ltd., £16,654 9s. 3d. The estimate of the chief officer of tramways was £12,120.

The following tenders have been received for the manufacture, supply, and delivery of four electrically operated car traversers for the central car repair depot and Norwood car-shed:—Mountain & Gibson, Ltd. (accepted), £1,907; Hurst, Nelson & Co., Ltd., £2,330; Heenan & Froude, Ltd., £2,381 10s.; Joseph Booth & Bros., £2,590; Appleby's, Ltd., £2,713. The estimate of the chief officer of tramways was £2,450.

Bermondsey.—The following tenders have been received for an electrically-driven pump capable of delivering 10,000 gallons per hour:—Dean & Beal, Ltd., £65; Siemens Bros. Dynamo Works, Ltd., £64 15s., alternative £66 10s., ditto £72 5s.; W. H. Allen & Co., Ltd., £65 10s.; Brush Electrical Engineering Co., Ltd., £63 10s., alternative £67 10s.; Gwynnes, Ltd., (accepted), £60; Mather & Platt, Ltd., £92; Worthington Pump Co., Ltd., £76, alternative £186, ditto £194; Lund Bros., £61 8s. Messrs. Siemens Bros.' tender was less 2½ per cent. and Messrs. Mather & Platts' £3 extra for impellers and guide tips.

COMPANIES' MEETINGS AND REPORTS

BRISTOL TRAMWAYS & CARRIAGE CO.—The report for the year ending December 31st, 1908, shows gross receipts of £265,362, and working and general expenses to £190,581, leaving a net revenue of £74,780 3s. 4d., as compared with £85,347 in the preceding year. This difference is due to the fact that, as indicated at the last general meeting, the directors have charged against revenue, instead of against reserve, the expenditure upon reconstruction of permanent way, which amounted during the year to £9,876, in addition to the outlay of £11,664 for ordinary repairs and maintenance usually borne by the revenue. After meeting interest on 4 per cent. mortgage debenture stock, 4½ per cent. mortgage debenture stock and on deposits, and bankers' interest, dividend on 4 per cent. preference shares for the year (subject to income tax), and interim dividend of 6 per cent. per annum (subject to income tax) for the half-year ending June 30th, there is a balance of £52,079, and the directors recommend a final dividend for half-year at the rate of 6 per cent. per annum (subject to income tax), adding £8,450 to reserve fund for contingencies and renewals. The company's investments at December 31st last, taken at market value, amounted to £196,543. The interest on investments has been carried direct to the credit of that fund, and with the addition now proposed of £8,450, the reserve fund will be further augmented to £204,993. The total number of passengers carried during the year was 46,652,389, as compared with 46,585,050 the previous year, an increase of 67,339. The extension of the tramways to Westbury-on-Trym was constructed during last summer, and opened for public traffic as far as Henleaze early in September, and throughout to the centre of Westbury on October 22nd. The meeting is on the 10th inst.

LONDON ELECTRIC SUPPLY CORPORATION.—The report for the year ended December 31st, 1908, shows that the profit on the working for the year is £53,209, against £46,520 last year. To this has to be added the amount brought forward, viz., £2,836, less interest on temporary loan, making a total of £54,565. Out of this the interest on debenture stock to December 31st, viz., £15,215, has been paid, leaving a balance of £39,350 to be appropriated. The Board propose a dividend of 6 per cent. on the preference shares (of which an interim dividend of 3 per cent. was paid on September 1st, 1908), and a dividend of 3 per cent. on the ordinary shares. The sum of £5,000 is added to reserve account, making a total of £62,500, leaving £3,408 to be carried forward. The number of units sold amounted to 13,160,130, as against 10,011,987 last year; the total costs per unit sold being 1·09d., as against 1·42d. last year—a reduction of 23 per cent. Out of the total number of units sold, 7,746,653, or 58 per cent., were sold for power (as distinguished from lighting) purposes, at an average price of 0·93d. per unit. The London Brighton and South Coast Railway commenced taking a supply for experimental working in connection with the electrification of their South London line on January 17th, and the Consulting Engineer of the railway has written saying that "the whole of the arrangements in connection with the trial runs work quite satisfactorily." The plant in connection with this important contract has been erected. Authority was granted on February 21st, 1907, to increase the capital of the company by an issue of 20,000 new preference shares of £5 each to provide this plant; but owing to the times being unpropitious for such issue, the necessary capital for this purpose has been partly provided by a temporary loan from our bankers. Now that Parliament has settled the question of power supply in London, an opportunity will be taken of making this issue for the purpose of paying off this loan and of providing further plant in response to increasing demands for power for electric traction and industrial purposes generally. The directors have to record with deep regret the death of their esteemed colleague, Sir William Pollitt. It is not proposed to fill the vacancy on the Board caused thereby at present. The meeting will be held on Tuesday, February 9th.

GREAT NORTHERN & CITY RAILWAY CO.—The total receipts for the six months ending December 31st last amounted to £58,827, and the cost of working to £21,813, being at the rate of 56·18 per cent. Inclusive of the balance brought forward from June 30th last, the net revenue amounts to the sum of £17,433, which is insufficient to meet the company's fixed charges for the half-year. The sum of £5,596, which has been provided from outside sources, has enabled the company duly to meet these charges. The number of passengers for the six months under review, including season-ticket holders, was 5,555,697, as against 7,543,174 for the corresponding period last year, and is the lowest of any corresponding half-year since the opening of the line. The number of local season tickets issued during the half-year was 3,178, as against 5,703 for the half-year ending December 31st, 1907. The directors' report states that the severity of the competition to which the company has been subjected for over a year continues unabated. Unquestionably the most important factor in the diversion of the company's traffic is the ever-increasing service of electrified tramcars provided by the London County Council, against which the company finds itself almost powerless. The meeting is to-morrow.

LIVERPOOL OVERHEAD RAILWAY CO.—The report states that for the half-year to December 31st, 1908, gross receipts were £37,167, and working expenses £29,158. The number of passengers carried was 5,167,464, compared with 5,804,629 in the corresponding period of last year. Of this large decrease 243,772 represents the reduction in the number of special return tickets issued to workmen. The decrease in traffic is attributable mainly to the depressed condition of trade, but there has also been increased competition of the Corporation tramways Mr. S. B. Cottrell, having resigned his position of engineer and general manager, Mr. E. J. Neachell, who has been acting as sub-manager and engineer for some years, has been appointed in his place. It will be seen from the accounts that the directors have been able to effect some reductions in working expenses; the effect of these will, however, be more apparent during the current year. The rolling stock and permanent way have been carefully maintained, and are in good working order and condition. There is a balance available for dividend of £7,886, out of which the directors recommend a dividend at the rate of 5 per cent. per annum (less income tax) on the preference shares, leaving a balance of £4,210 to be carried forward. The meeting is on the 9th inst.

SIEMENS & HALSKE A.G.—The report for the year ended July 31st, 1908, states that the year has been a favourable one, the gross income having risen some 15 per cent. over that of the previous year. The production of tantalum lamps has increased considerably without any falling off in the production of carbon filament lamps, and the orders for the new year show that the tungsten lamp will not cause any decrease in production. New sections of the Berlin elevated railway were completed during the past year, and among the contracts for work in the present year are the underground railway from Nollendorf to Schöneberg and the suburban lines of Hamburg. The net profit for the past year amounted to, approximately, £484,000, of which £73,000 is transferred to the reserve fund, £30,000 paid out as bonuses, £17,500 to management fund, and £290,000 in five per cent. and six per cent. dividends.

ELEKTRIZITATS-A.G. VORMALS SCHUCKERT & CO.—According to the report for the year ended July 31st, 1908, the net profits amounted to, approximately, £193,000, which is to be divided as follows:—Reserve fund, £6,600; directors' fees, £1,300; five per cent. dividends, £125,000; carried forward, £60,100.

SIEMENS SCHUCKERT WERKE GES.—The report for the year ended July 31st, 1908, states that the net profit amounted to, approximately, £510,000. Of this nearly £450,000 is to be laid out in 10 per cent. dividends. The number of dynamos, motors, and transformers supplied by the company in the past year was over 50,000, with a total capacity of over one million kilowatts.

METROPOLITAN RAILWAY CO.—The report and accounts for the half-year ending December 31st show receipts amounting to £376,286, and expenses to £202,044, leaving a profit of £174,242. Compared with the corresponding half-year of 1907 the receipts show an increase of £28,635, and the expenses an increase of £10,084. After providing for the interest upon the debenture stocks and other fixed charges, and placing £17,000 to the electrical renewal and depreciation fund, there is a balance of £127,534, which will permit of the payment of the dividends upon the preference stocks, and leave a balance of £23,024 available for dividend upon the ordinary stock. The directors recommend a dividend upon the ordinary stock at the rate of 10s. per cent. per annum, and to carry forward the balance of £8,694. The Surplus Lands Committee announce that the dividend on the surplus lands stock, for the past half-year, will be at the rate of £3 per cent. per annum. In crediting the electrical renewal and depreciation fund with £17,000, and thus strengthening the financial position of the company, the directors believe that they are pursuing a wise policy, especially having regard to the fact that a considerable proportion of the increased revenue of the half-year was derived from a special source, viz., the Franco-British Exhibition traffic, and also bearing in mind that it has not been possible during the past two or three years to build up that fund to the extent that the Board considers is desirable. The fund in question now stands at £47,450. The installation of automatic signalling on the inner circle line will be completed during the current half-year. The electrical plant and machinery have worked smoothly during the past half-year, and the current has been produced at an exceptionally low figure per unit. The total number of passengers carried during the year was 99,846,735, compared with 96,859,108, but a large portion of the increase was due to the Franco-British Exhibition.

At the meeting on Thursday, the report and accounts were adopted. Sir Charles McLaren, Bart., M.P., chairman of the company, who presided, said that carriage and wagon repairs showed an increase of £1,382, due to the fact that they had lately been renovating a considerable number of old compartment carriages with a view to running them by means of

Digitized by Google

electric locomotives between Baker Street and Harrow. Traffic expenses showed an increase of £2,537, due partly to extra work in connection with the Franco-British Exhibition and partly to higher Sunday pay to the staff. General charges showed the rather heavy increase of £3,324. Of this £1,392 represented the half-year's contributions to the new staff pension fund. The other item of increase was for advertising, which was large in consequence of special advertising in connection with the Exhibition. Rates and taxes showed an increase of £910, and they were feeling very keenly the heavy burden of local rates. The amount paid under this head in a year was equivalent to almost 1 per cent. on the ordinary stock. Considering that no small part of this money went toward the upkeep of roads, of which competing omnibuses had free use, they had very just ground for complaint. The whole question of the taxation of railway companies, especially in cities and large towns, was one which the legislature might very properly deal with. In conclusion he mentioned that the Board felt that the period of depression was passing away, and that as there was no immediate capital expenditure necessary, they felt justified in looking forward to a gradual but decided improvement. Mr. W. R. Lawson criticised the management of the line, and advocated the abandonment of the two minutes' service, which would allow of less mileage being run per annum and increase the amount available for dividends. He moved an amendment, which was not accepted, that a dividend of 1 per cent. be paid.

LONDON, BRIGHTON & SOUTH COAST RAILWAY CO.—The half-yearly report of the directors states that the electrical equipment of the South London line is now complete from Battersea Park to Peckham Rye, and that the experimental working of this section has been very satisfactory.

DUBLIN UNITED TRAMWAYS CO.—The report for the half-year ended December 31st, 1908, shows that the amount available for division is £43,249, out of which it is recommended that dividends be paid for the half-year at the rate of 6 per cent. per annum on the preference shares, and at the rate of 6 per cent. per annum, free of income tax, on the ordinary shares. The dividends recommended will absorb £35,100, leaving £8,149 to be carried to next account. The directors do not propose to add anything to reserve, but have charged against revenue the whole of the cost incurred during the half-year to complete the relaying of the Dalkey line to Blackrock. Special meetings will follow the ordinary meeting on Tuesday next to authorise an increase in the capital by £100,000 in ordinary shares. The directors do not contemplate the issue of any more of this sum than may be needed to adjust the capital account now over-expended by £22,657 19s., and for such other capital expenditure as may from time to time be required; also, if desirable, to enable them to invest the reserve funds which are now being used as capital in the company's business.

CENTRAL LONDON RAILWAY CO.—The report for the half-year ended December 31st, 1908, states that the amount of capital expended during the half-year was £8,268. The chief item is for the extension of the line from Shepherd's Bush to Wood Lane, which was completed in May of last year. Compared with the corresponding period in 1907 there has been an increase of £50,307 in the revenue receipts, and of £5,235 in the working expenses. The balance carried to net revenue is £104,693. After providing for interest on the debenture stock and other payments, there remains a balance of £118,384. The directors recommend the declaration of the following dividends: On the undivided ordinary stock, 3½ per cent. per annum for the half-year; on the preferred ordinary stock, 4 per cent.; on the deferred ordinary stock, 2½ per cent. per annum for the whole year. These will absorb £58,046, leaving a balance of £60,338. The directors recommend that £20,000 of this sum be credited to the reserve fund, increasing the total of the fund to £95,083, the balance remaining of £40,338 to be carried forward to next half-year. Since the close of the Franco-British Exhibition there has been a marked falling off in the company's daily business, due, doubtless, to the largely increased facilities for cheap short distance travelling afforded by the motor and horse omnibus competition on the Oxford street route. The directors are endeavouring to encourage the use of the railway by affording a more frequent service of trains, but it may also be necessary to consider the advisability of making a change in the present scales of fares in order to meet this surface competition on more even terms. The through bookings with other companies are progressing satisfactorily, and show that the convenience afforded is appreciated by the public. The number of passengers carried during the half-year was 21,996,623, compared with 19,901,750 in the corresponding period of 1907. The total number carried during the year 1908 was 41,898,373, compared with 36,907,491 in 1907. There was an increase of 5,350,003 in the number of passengers carried during the half-year. The average receipt per passenger is 2·03d., as compared with 2·01d. in the half-year ending December, 1907. The cost per passenger is 1·02d., as compared with 1·28d. in the corresponding period. A Bill has been deposited in Parliament to empower the company to extend their line from the Bank Station to and under the Liverpool Street Station of the Great Eastern Co., with a connection to the adjacent Broad Street Station of the North London Co. It also provides for exchange subways to be constructed between the Holborn Station of the Great Northern, Piccadilly & Brompton Co., and the British Museum Station of the Central London Co., and between the public subway at the Bank Station of the Central London Co. and the booking-hall of the City & South London Co. in Lombard Street. These additional connections will enable the companies concerned to further extend and improve the arrangements for through bookings at present in operation. The Bill further provides for the raising of £330,000 additional share capital, with borrowing powers of £110,000. The meeting is to-day (Thursday).

MEXICAN LIGHT & POWER CO.—The report for 1908 states that the actual and prospective demands for power have increased beyond the directors' most sanguine expectations, and to meet these demands it has been decided to double the capacity of the present hydro-electric plant at Necaxa during the next three years, and to bring into the Necaxa Basin, by a series of diverting and storage dams, canals, and tunnels, the waters of the Lower Tenango, Nexapa, and Catepuxtla rivers, which are included in the water rights granted to the company by the Government of Mexico. The gross earnings for the year 1903 were $2,938,474 gold, and the operating and maintenance expenses $1,080,570. Inasmuch as surplus earnings to the amount of $1,486,710 gold were accumulated prior to December, 1903, during the period of construction, the Board, rather than distribute this surplus in dividends, has deemed it advisable to write off the following sums:—For increased cost of construction due to drought and other special conditions, $478,789; appropriation for depreciation in transformers, meters, electric supplies, &c., acquired on purchase of other companies, $100,000; appropriation for bad and doubtful debts due to the company, $47,414. Out of the earnings of the past year 3½ per cent. has been paid in dividends on the ordinary shares, and on December 31st last a balance of $910,323 gold was carried forward.

MISCELLANEOUS CITY NOTES

SOUTH METROPOLITAN ELECTRIC LIGHTING & TRAMWAYS CO.—The directors have announced that, pending the completion of the accounts to December 31st, they have decided to postpone the payment of the preference dividend for the second half of the year.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—A dividend of 10 per cent. per annum (less tax) for the half-year to December 31st, 1908, has been recommended.

ST. JAMES'S & PALL MALL ELECTRIC LIGHT CO.—The directors recommend a dividend on the preference shares of 3s. 6d. per share, and 5s. per share on the ordinary shares, for the half-year to December 31st, making, with the interim dividend paid on August 8th last, a total distribution of 7 per cent. on the preference and 10 per cent. on the ordinary shares for the year.

NATIONAL TELEPHONE CO.—The directors have resolved, subject to final audit, to recommend the following dividends for the half-year to December 31st, 1908, after payment of the dividends on the preference shares:—At the rate of 6 per cent. per annum on the preferred stock, and at the rate of 6 per cent. per annum on the deferred stock, less income tax, carrying £155,000 to reserve and about £10,000 forward.

METROPOLITAN DISTRICT RAILWAY CO.—A dividend of 1¾ per cent. is recommended on the 4 per cent. guaranteed stock. This is the same as last year.

CENTRAL ELECTRIC SUPPLY CO.—A dividend of 5 per cent. (5s. per share) is recommended on the ordinary shares for 1908, carrying forward £23.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—Subscriptions have been invited to an issue of £50,000 six per cent. cumulative second preference shares of £1 each at par. The issue is to meet the cost of the normal expansion of the company's business.

MEXICO TRAMWAYS CO.—An issue of £1,250,000 six per cent. 50-year mortgage debenture bonds at 95½ has been advertised during the week. The bonds will be secured by a trust deed in favour of the National Trust Co., Ltd., of Toronto, dated February 1st, 1909.

VICTORIA FALLS POWER CO.—A meeting will be held on February 18th, when a resolution, changing the name of the company to the Victoria Falls & Transvaal Power Co., Ltd., will be moved. It is stated that the whole of the underwriting of the new issue of capital, registered in connection with the Rand Mines contract, which has been entered into in conjunction with the Rand Mines Power Co., has been completed.

Railway Electrification in Canada.—It is announced that the electrification of the Canadian-Pacific Railway will be confined to the Rocky Mountains section of the line. Coal is very cheap in that district, but water-power is also plentiful, and in view of the heavy gradients on that part of the line, and the superiority of electric locomotives for maintaining high speeds under such conditions, it has been decided that electrification is desirable.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Notice is given of the payment of a first and final dividend of 2s. in the £, with four per cent. interest, in the bankruptcy of E. P. Oliver, lately trading as Messrs. Newington, Priddle & Co., electrical engineers, 50 Great Sutton Street, Goswell Road, London.

A petition for the winding up of Engineering Instruments, Ltd., will be heard before Mr. Justice Swinfen Eady, at the Royal Courts of Justice, London, on February 9th. The petition is at the instance of Messrs. Davis and Timmins, screw manufacturers, York Road, King's Cross, London.

SELL'S TELEGRAPHIC ADDRESSES DIRECTORY.—The 24th yearly issue of Mr. Sell's Telegraphic Addresses Directory is now ready.

BITUMEN.—The British Electrical Trade Supply & Bitumen Co. inform us that they have terminated their agreement with Mr. H. H. Bishop, and that after January 31st he will not be connected with them in any way. Mr. A. E. H. Dussek will in future call upon buyers in London and the South, and, having visited Trinidad, he is able to give any information required with regard to Trinidad bitumen, compounds, &c.

APPOINTMENTS AND PERSONAL NOTES

The staff of the Exeter Electricity Department was entertained at dinner last week by the City Electrical Engineer, Mr. H. D. Munro, in order to meet Mr. T. P. Wilmshurst, Borough Electrical Engineer at Derby, who was formerly Chief Engineer to the late Exeter Electric Light Co. Several other old members of the staff were also present.

The death is announced of Mr. W. E. Halton, who until December, 1905, was chief superintendent of telegraphs and telephones in the Manchester district.

Messrs. Swinburne, Cooper & Baillie have joined with Messrs. O'Gorman & Cozens-Hardy. The new firm is entitled Swinburne, O'Gorman & Baillie, and will continue to practise as consulting engineers in electrical, automobile, and general work, at 82 Victoria Street, London, S.W. The partners are: J. Swinburne, M. O'Gorman, G. H. Baillie. Mr. W. R. Cooper has severed his connection with Messrs. Swinburne, Cooper & Baillie, and he will continue to practise as consulting engineer in electrical and mechanical engineering and experimental work at the above address.

Mr. W. T. Humphrey has been appointed canvasser to the Fulham Electricity Department, at a salary of £2 10s. per week. There were 127 applications.

A sub-committee of the Gloucester Electricity Committee recommends that a month's notice be given to Mr. R. G. White, the electrical engineer, and that a week's salary, in lieu of notice, be given to the chief assistant electrical engineer and station superintendent. The Council has confirmed the recommendation.

Telegraph Traffic.—Telegrams can now be sent to French and Dutch Guiana and Brazil via Martinique, as the cable between that island and Paramaribo (Dutch Guiana), which was interrupted on the 11th ult., was restored to working order on the 29th ult. The French Cable Company, to whom the cable belongs, have their own repairing steamer stationed in the Caribbean Sea. The cable between Zanzibar and Mombassa ceased operating on the 27th ult., but a speedy repair was effected on the 29th ult. The Falmouth-Bilbao, Tourane-Amoy, Malta-Zante, Pontianak-Saigon, and Medan-Penang cables have not yet been repaired.

According to the *Matin*, M. Cruppi, Minister of Commerce, will shortly put a proposal before the Cabinet to introduce a Bill to compel French shipping companies to equip all mail steamers above a certain tonnage with wireless telegraphic installations.

The value of wireless telegraphy to passenger steamers was again demonstrated on Sunday last, when the liner *St. Louis* reported itself temporarily disabled, due to a damaged rudder, and by establishing communication with the shipping agent by wireless all anxieties were allayed.

"Gas-tight" Switchgear.—On Thursday last an inquest was held in Wakefield on the bodies of J. Platt and H. Meredith, miners, of Pontefract, whose deaths resulted from burns sustained at the Ackton Hall Colliery, Featherstone. The men were working in a heading, when Platt switched off a 4 h.p. fan, the motor and switch-box of which were supposed to be gas-tight. An explosion followed, however, and as the men's lamps were found to be in good condition, it was concluded that the switch-box was the cause. Mr. H. Pickering, Chief Inspector of Mines for the Yorkshire District, pointed out that there was an aperture between the lid and the edge of the box. The joint was supposed to be rendered gas-tight by the insertion of a rubber strip round the flange of the lid. This, however, was broken, and as the rim was only 5/16 in. wide there was little chance of a gas-tight fit. The jury found that death was due to burns accidentally received through an explosion, the explosion being caused by the entrance of gas into a switch-box which was not at the time gas-tight. A more regular inspection of such apparatus was recommended.

TENDERS INVITED.

COUNTY BOROUGH OF SALFORD.

ELECTRICITY DEPARTMENT.

Annual Contracts for Supply of Stores, &c.

TENDERS ARE INVITED for the following Materials in such quantities as may from time to time be required, between the 1st April, 1909, and the 31st March, 1910.

SPECIFICATION NUMBER AND LIST OF REQUIREMENTS.

1. Cables.
2. Cable Accessories.
3. Refined Trinidad Bitumen.
4. Cable Conduits, Stoneware and Fibre Pipes, Asphalte Bridges, &c.
5. Wood Troughing, Bends, &c.
6. Cement, Lime, Bricks, &c.
7. House Service Cutouts.
8. Electricity Meters.
9. Maximum Demand Indicators.
10. Gravity Type Ammeters.
11. Circuit Breakers and Ironclad Double Pole Switches.
12. Soda Ash.
13. Switches, Fuses, and Arc Lamp Globes.
14. Carbon Filament Glow Lamps.
15. Arc Lamp Carbons and Motor Carbon Brushes.
16. Electric Motors.
17. Motor Starters.
18. Iron Castings.
19. Brass and Gun-Metal Castings.
20. Iron and Steel Bars, Plates, &c.
21. Ironmongery.
22. Wrought Iron Tubes and Fittings.
23. Druggists' Sundries.
24. Timber.
25. Wood Fittings.
26. Engine Room Stores.
27. Engine Oils.
28. Carting.
29. Economiser Cleaning.

Specifications, Forms of Tender, and all requisite information, may be obtained from Mr. Victor A. H. M'Cowen, M.I.E.E., the Borough Electrical Engineer, Electricity Works, Frederick Road, Pendleton.

A deposit of 10s. is required on each of the following Specifications, viz., Nos. 1, 4, 7, 8, 9, 10, 11, 14, 16, and 17, which will be returned on receipt of a *bona fide* Tender. Duplicate copies of any Specifications will be supplied at a charge of 2s each.

Sealed Tenders, endorsed 'Tender for Contract No. . . .,' accompanied by Samples where required, and addressed to the Chairman of the Electricity Committee, must be delivered at the aforesaid Offices of the Borough Electrical Engineer before Noon on Monday, the 15th February, 1909.

The Committee do not bind themselves to accept the lowest or any Tender.

Town Hall, Salford.
2nd February, 1909.

L. C. EVANS,
Town Clerk.

WESTMINSTER ELECTRIC SUPPLY CORPORATION, LIMITED.

HORSEFERRY ROAD STATION.

THE CORPORATION are prepared to receive Tenders for the Supply, Delivery, and Erection at their Horseferry Road Station, of the following:—

Specification 9. Combined High and Low Tension Switchboards.

Specification 10. Low Tension Switchboard and Battery Boosters.

Copies of these Specifications, along with drawings and general conditions, can be obtained on and after February 5th, from Messrs. Kennedy & Jenkin, on payment of a fee of Two Guineas for each Specification, which will be returned on receipt of a *bona fide* Tender.

Tenders, which should be written on the forms at the end of the Specifications, must be enclosed in a sealed envelope, endorsed on the outside, "Electric Plant, Tender to Specification ——," and sent to the Secretary of the Westminster Electric Supply Corporation, Eccleston Place, Eccleston Street, Belgravia, S.W., so as to be received by him before 10 o'clock on the 26th of February.

In the case of Specification 10, the Battery Boosters and Low Tension Switchboard may be tendered for separately.

The Corporation do not bind themselves to accept the lowest or any Tender, and no allowance whatever will be made for expenses incurred in the preparation of a Tender.

KENNEDY & JENKIN.

17, Victoria Street,
Westminster, S.W.

For other Advertisements of Tenders Invited, see pp. vii *and* x.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Jan. 28th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

26,762/07, **Continuous-current Transformer.** W. SCHÄFFER. This specification describes a two-pole single-winding machine for supplying arc lamps or low-voltage metal filament lamps from a high-voltage continuous-current supply. The two main brushes of the commutator are connected to the main supply, and the low voltage circuit is connected across one main brush and either one or two connected auxiliary brushes. One part of the armature acts as a motor, and the other part as a dynamo. In order to obtain sparkless commutation the poles must be divided, and in such proportion as the armature is divided. For arc-lamp circuits, the machine can be made to deliver constant current at varying voltage by winding series coils on both parts of the divided poles, so that with increasing current the dynamo field is weakened and the motor field strengthened. A constant voltage with varying current for incandescent lamps is obtained by a reverse action. One claim, five figures.

4,685/08, **Terminals and Connecting Leads.** S. R. RIDGWAY, F. J. RIDGWAY, and C. M. BRUNT. According to this invention, it is proposed to adapt the well-known glove-fastening device, in which a spring cap is snapped over a bulbous end or knob, to electrical connection purposes. The terminal screw or the nut is provided with a stud or knob, and the end of the connecting lead with a spring cap enclosed in insulating material. The snap action may be effected by spring tongues in the cap or by splitting the knob. Two claims, four figures.

5,611/08, **Motor Starter.** BRITISH THOMSON-HOUSTON CO., LTD. (*General Electric Co., U.S.A.*) This patent is for an automatic motor starter, in which the operating solenoid is composed of two coils, a holding coil and an operating coil, the latter being automatically cut out of circuit when the controlling arm reaches the running position. A switch for closing the motor circuit is provided, and this is actuated by the holding coil immediately the solenoid circuit is completed. The controlling arm, which commences to rise at the same moment, is retarded by a dashpot as usual. Two claims, one figure.

10,341/08, **Supports for Metal Filaments.** BRITISH THOMSON-HOUSTON CO., LTD. (*Allgemeine Elektricitäts Ges.*) In a previous patent a form of support for metal filaments, consisting of a pivoted wire anchor provided with a guide loop through which the filament passes, was described. The only tension keeping the filament in place was the weight of the anchor. When the filament contracts abnormally, however, it breaks when held in this way, as the movement of the anchor is limited. According to the present invention, the anchor is coiled round the projection of the pedestal to which it is attached; and after the free movement is completed, this coil, being resilient, permits of further contraction of the filament. Two claims, three figures.

13,257/08, **Electric Furnace.** H. HELBERGER. The furnace described in this specification comprises an ordinary transformer with means for varying the number of turns in the primary circuit, and a crucible which is clamped between carbon contact pieces in the secondary circuit. The crucible, made from a mixture of clay and graphite, is constructed thinner at the central portion, or the resistance of the central portion is increased by reducing the quantity of graphite in the composition of that part, in order to concentrate the heat. To remove the carbon from the inside surface of the crucible it is heated in a stream of oxygen, or is treated with a silicate or nitric acid and potassium chlorate. Six claims, six figures.

13,678/08, **Compound Conductor for Alternating-currents.** A. WOLFF. Many attempts have been made to produce a conductor which shall have great self-induction, but shall not be subject to the action of the skin effect. Pupin coils inserted with this object have not always been successful owing to a reflex action and the sensitiveness with respect to magnetic influence. Compound conductors of copper and iron have also proved impracticable. According to this invention, it is proposed to use a conductor comprising a magnetic steel core and a non-magnetic manganese steel outer case, or alternate layers of magnetic and non-magnetic steel. Four claims, three figures.

17,530/08, **Cables for Use in Mines.** LAND-UND SEEKABELWERKE AKT.-GES. Danger exists in mines where explosive gases are present, owing to the possibility of short-circuits or the sudden breaking of the circuit, and the consequent arcing if a power cable is damaged. As a safeguard against such arcing, cables for mines are, according to this invention, provided with two or more concentrically arranged auxiliary conductors, and the outermost two are separated by a thin layer of pliable insulating material. If the cable is squeezed or subjected to any form of mechanical strain, the outer conductors will be short-circuited before the main conductors, and as these are arranged to operate a cut-out device, no arcing will occur if the cable is entirely destroyed. One claim, one figure.

17,618/08, **Manufacture of Metal Filaments.** W. C. ARSEM. This invention relates to a process for the manufacture of tungsten filaments, and consists in first mixing very finely divided WO_3 with graphitised lampblack and a solution of ceresene, rosin, and gilsonite, in benzole. To ensure a uniform mixture, the product is passed several times through a fine aperture under pressure, and finally squirted through a circular die. The squirted threads are baked at a temperature of about 350° C. to drive off the volatile components. They are then packed in powdered silica in graphite troughs, and fired to a temperature of 1,500° C. to complete the reduction, and to sinter them together. Three claims.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: JONES [Arc lamp] 5,829/08.

Distributing Systems Cables and Wires, Insulating Materials, &c.: SIEMENS BROS. DYNAMO WORKS, LTD., AND LYDALL [Detection of faults in A.C. high-tension overhead lines] 23,340/08.

Dynamos, Motors, and Transformers: DUPONT, AND HARLÉ ET CIE [Continuous-current motors] 17,852/08.

Electrometallurgy and Electrochemistry: HERRENSCHMIDT [Manufacture of aluminium] 433/08; JACOB [Manufacture of acetate of soda] 726/08; BISMARCKHUTTE CO. [Refining of steel] 6,029/08; BOUNEAU [Furnaces] 8,904/08; LONDON ELECTRON WORKS CO. AND KARDOS [Apparatus for use in recovery of tin] 17,113/08; HUBBELL AND FULLER [Reversible battery] 17,331/08; DODGE [Furnaces] 17,863/08.

Ignition, Electric: ZÄHRINGER, 7,014/08: WOOD AND WOOD [Anti-vibrating lead terminal] 10,820/08; HALL [Sparking plug] 20,091/08; RUTHARDT & CO. [Rotary make-and-break] 21,195/08.

Incandescent Lamps: PLANCHON [Manufacture of metal filaments] 5,040/08; GREENWOOD [Lamps for motor-cycles] 5,078/08; BRITISH THOMSON-HOUSTON CO. AND ROBERTSON, 11,460/08.

Instruments and Meters: FENNELL AND PERRY [Photometer] 6,971/08; HOOKHAM AND HOLDEN [Electrolytic meters] 10,614/08; SIEMENS BROS. DYNAMO WORKS (*Siemens-Schuckert-Werke Ges.*) [Pressure and speed controlling devices] 19,890/08.

Switches, Fuses, and Fittings: KENNEDY, MCGREGOR AND MOUNTFORD [Switches] 2,175/08; DIXON [Controller for electrically-operated bascule bridge] 4,307/08; GROSE and LAMBERT [Fuso boxes and holders] 13,515/08; OPSAHL [Oil switches] 19,871/08.

Telephony and Telegraphy: BAKER [Transmission of half-tone and line photographs] 9,518/08; BÜSCHELBERGER [Inductors for telephone apparatus] 15,370/08.

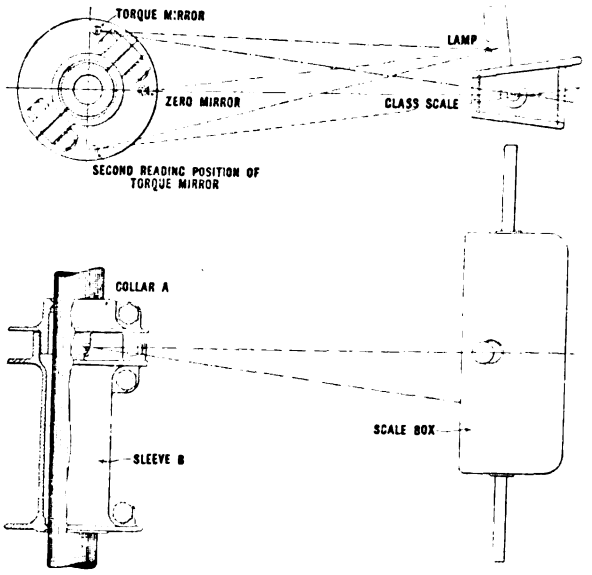
Traction: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Traction system] 7,434/08; DE SAINTE-CLAIRE [Variable-speed gear for electric automobiles] 9,877/08; THAYER [Electrically-propelled vehicles] 10,687/08; CURRAN and KELLEY [Trolleys and collectors] 13,299/08; SIEMENS AND HALSKE AKT.-GES. [Switches for setting points and signals electrically] 16,164/08; COOPER [Regenerative control] 18,275/08.

Miscellaneous: BATTY and BATTY [Liquid magnetic compasses] 4,885/08; FAIRWEATHER (*Aktiebolaget L. M., Ericson & Co.*) [Driving electric secondary clocks] 22,713/08; HAILWOOD [Apparatus for igniting miners' lamps] 25,597/08.

The following Specifications are open to Inspection at the Paten Office before Acceptance, but are not yet published for sale.

STOLZ and VIGGARS [Telephone apparatus] 13,875/08; WEISSMANN [Fitting incandescent lamps] 18,233/08; AKT.-GES. BROWN, BOVERI ET CIE [Starting and governing ring-spinning frames] 26,223/08; CONRAD [Transformers for vapour devices] 26,555/08; SOULE [Control of motors] 28,017/08; LAIGLE [Lamp filaments] 28,435/08; KUNKEL [Dynamo-electric machines] 404/09; SIEMENS-SCHUCKERT-WERKE GES. [Resistance coils of covered wire] 580/09.

Expiring Patent



The following patent expires during the current week after a life of fourteen years:—

2,915 of February 9th, 1895. **Controller for Traction Motors.** J. DEVONSHIRE (BRITISH THOMSON-HOUSTON CO.) (*E. D. Priest.*) This patent is for a double-barrel controller for traction motors, and a modified method of series-parallel control especially adapted for heavy railway work. One barrel of the controller varies the connections of the motors, and the other, which is geared with the first, inserts resistances in series before making or breaking the circuit, and also in between the various speed steps, in order to prevent rushes of current. The latter barrel makes a whole revolution for each step of the former. There is an "off" position between each running position.

Digitized by Google

A NEW TORSION METER

A NEW piece of apparatus for determining in a simple and accurate manner the horse-power transmitted by turbine and other shafts has recently been put on the market by Messrs. Siemens Brothers & Co., Ltd., of 12 Queen Anne's Gate. The principle of the apparatus, which was designed by Professor

HOPKINSON-THRING TORSION METER.

Hopkinson and Mr. Thring, is a differential one, and consists in the observation of the twist between two adjacent points on the shaft by means of two beams of light projected on to a scale from a fixed and a movable mirror. The beam projected on the scale by the fixed mirror is taken as the zero point, whilst the beam projected by the movable mirror indicates the amount of torque on the shaft. Both mirrors revolve with the shaft, but even at moderate speeds the reflections appear as continuous lines of light across the scale, and there is, therefore, no difficulty in taking readings.

A drawing, showing the construction of the apparatus, is given in the accompanying figure. A collar *A*, clamped to the shaft of which the torque has to be measured, is provided with a flange projecting at right angles to the shaft and an extension.

A sleeve *B*, provided with a similar flange and extension at one end, is clamped at its further end on to the shaft in such a manner that its flange is close to that on the collar *A*, whilst its extension overlaps that of the collar *A*, on which it is supported to keep it concentric. Both the collar and sleeve are quite rigid, and, therefore, when the shaft is twisted by the transmission of power, the flange on the sleeve *B* will move relatively to that on the collar *A* by an amount equal to that between the two parts of the shaft on which these fittings are clamped. This movement is made visible by a system of mirrors mounted between the two flanges, which reflect a beam of light projected from a lantern on to a ground-glass scale.

With the arrangement shown a reflection will be received from each mirror of every half-revolution of the shaft, but in cases where the torque is subject to much variation during one revolution a second system of mirrors may be arranged at right angles, so that four readings can be taken during each revolution.

If the position of the apparatus becomes altered relatively to the scale, owing to the warming up of the shaft or from other causes, this is indicated immediately to the observer by an alteration in the position of the zero as reflected by the fixed mirror. Hence the zero can be adjusted by moving the scale so that its zero coincides with the reflection from the fixed mirror. It will readily be understood that a movement of the torque mirrors can only occur through a relative movement of the two flanges, so that vibration will not influence the readings in any way. The constant of the instrument, viz., the factor which, when multiplied or divided into the product of the torsion-meter reading and the revolutions, gives the horse-power, may be calculated within 2 or 3 per cent., if the section of shaft within the instrument is uniform. But a direct calibration of the shaft with the instrument in position is recommended. This is effected easily by applying a known twisting couple. The apparatus is made in a number of sizes for shafts up to 16 in. diameter.

A NEW AUTOMATIC TELEPHONE CALL-BOX

THE increasing use of the telephone call-office has revealed to the National Telephone Co. and the Post Office that, by the present method of working, the operator has to waste an unnecessary amount of time on each call. According to the present procedure, the person desiring to call up a subscriber, on first entering the call-office, takes off the receiver (which operation lights a lamp at the exchange in the usual way, and calls the attention of the operator), and states the number he requires. The exchange operator then takes the usual steps to call up the wanted subscriber, and, having obtained his reply, asks the caller to insert the charge in the slot provided, and to turn the handle after the insertion of each penny, to give the usual buzzer signal. It often happens that the caller has not the pennies ready to insert, and in some cases he has not even taken the precaution to see that he has any change, with the result that both the exchange and subscriber are kept waiting for a considerable time. The apparatus which we describe below has been devised for the purpose of preventing this delay, and is intended to be substituted for the present well-known "money-box" with its handle.

The chief advantage of the new arrangement is that the caller has to insert the fee before he can communicate with the exchange, so that he can be put on to the wanted subscriber as soon as the latter answers, and this necessitates an auxiliary device by means of which the operator can return the coins to the caller in the event of the call being ineffective, *i.e.*, of the subscriber being engaged.

A careful inspection of the diagram given in Fig. 1, and the views of the mechanism given in Fig. 2, will enable the reader to follow the working of the device. These photographs and the diagram represent a box designed to take the usual metropolitan fee of twopence.

The first thing the caller has to do is to put his money in the slot. The two pennies fall into the trough in

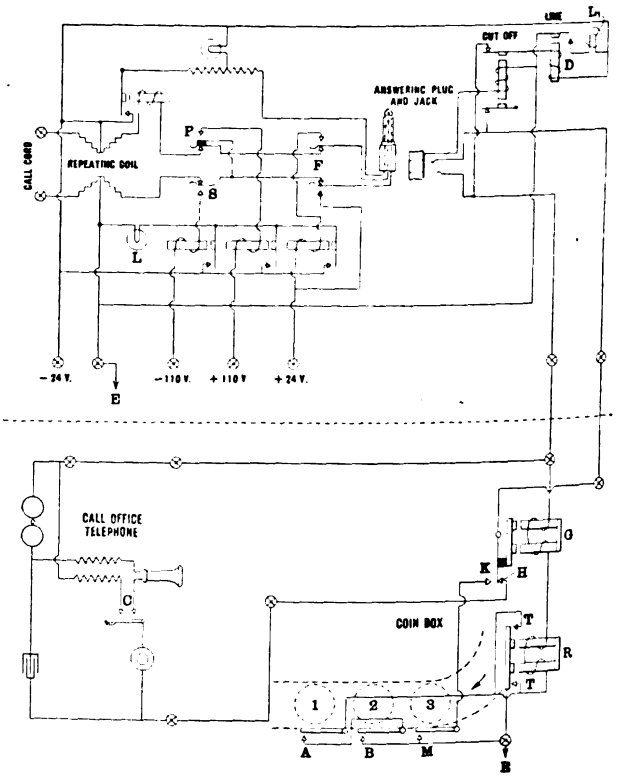


FIG. 1.—DIAGRAM OF CONNECTIONS.

the position indicated in the diagram. Springs, fitted in the bottom of the narrow trough, are depressed

Digitized by Google

by the weight of the coins, and make contact at A and B. As these contacts are in series with the earth connection, the earth circuit is not complete until both pennies have been inserted. When a coin rolls on to any spring, it causes a little catch to fall into position behind so as to prevent the next coin from overlapping it. The earth connection being now completed, the caller lifts the receiver and closes the circuit at C, and this operates the line relay D at the exchange, which in turn causes the lamp L to light up. The exchange operator then plugs in to the call-office line in question, and the normal procedure is gone through, with the exception that the caller is not asked to put any coins in the box unless there is some reason for an additional charge. In the latter case, the exchange operator asks him to insert a third coin, and this falls into the position indicated in the diagram. To test whether the coin has been inserted, the exchange operator depresses the "test" key F. This causes the polarised magnet G to break contact at H, and make contact at K, with the result that the lamp L glows if there is contact at M; and contact at

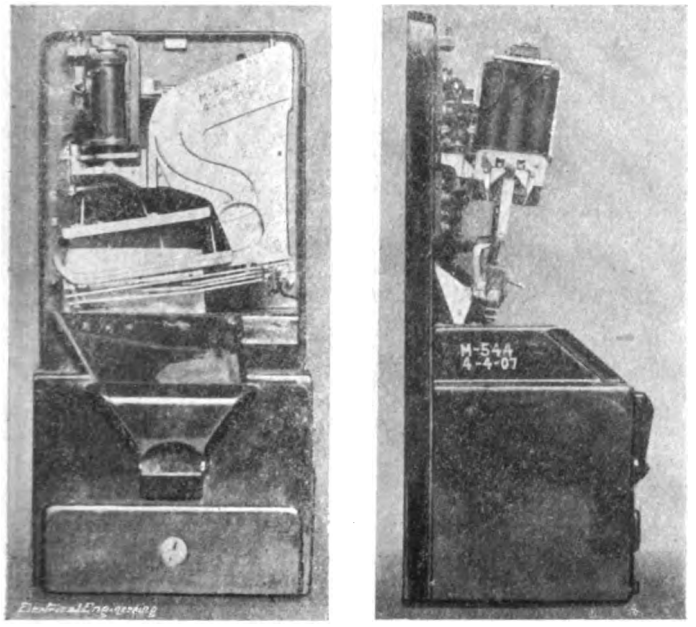

FIG. 2.—COIN-BOX FOR AUTOMATIC CALL OFFICE.

M can only be produced by the insertion of a third coin. Satisfied that the third coin is there, the operator releases the key F, and the lamp circuit is broken at K, while the speaking circuit is made again at H. When the conversation is finished, the exchange operator depresses the "deposit" key P, and this causes the polarised magnet R to rock its armature, which, as can be seen from the illustrations, is attached to the top of the coin trough. The top is rocked in an inward direction, and the coins fall into the money-box.

If, on the other hand, the call has been ineffective, the exchange operator depresses the "return key" S, which connects the magnet R to the opposite pole of the battery. In consequence, the top of the trough is rocked in an outward direction and the coins fall on to the top of the box, from which they slide into the little cup seen on the front of the case. The function of the retaining contacts at T is to prevent a vibrating motion of the top of the trough. This they do by retaining the earth circuit, otherwise broken at A and B while the coins are falling.

It should be mentioned that, whereas the polarised magnet R requires a comparatively large E.M.F. to operate it, the magnet G is very sensitive. This prevents the calling or test current from having any effect on the magnet R, and enables all the above operations to be performed through the ordinary telephone circuit without any additional wires, by means of batteries of different voltages. Thus it will be seen from the diagram that, for calling and for testing the third coin, the line is connected to a negative or a positive terminal respectively of 24-volt batteries. A "negative" current has no effect on the testing mechanism, although the coils of the relay magnet G carry negative currents as well as positive currents. For operating the depositing and returning mechanism, the line is connected to a positive or negative terminal respectively of 110-volt batteries, as a comparatively strong current is required in the coils of the polarised magnet R to rock the armature and drop the coins.

The apparatus above described has been devised and is manufactured by the Western Electric Company, and it has been used tentatively with satisfactory results by the National Telephone Co., and more recently by the Post Office.

THE REASON CO.'S TIME SWITCH

THE accompanying illustrations show the details of a time switch which has been introduced by the Reason Manufacturing Co., of Brighton, to meet the demand for a time switch which will open or close a circuit without the necessity for current being supplied to its own winding gear. The power for

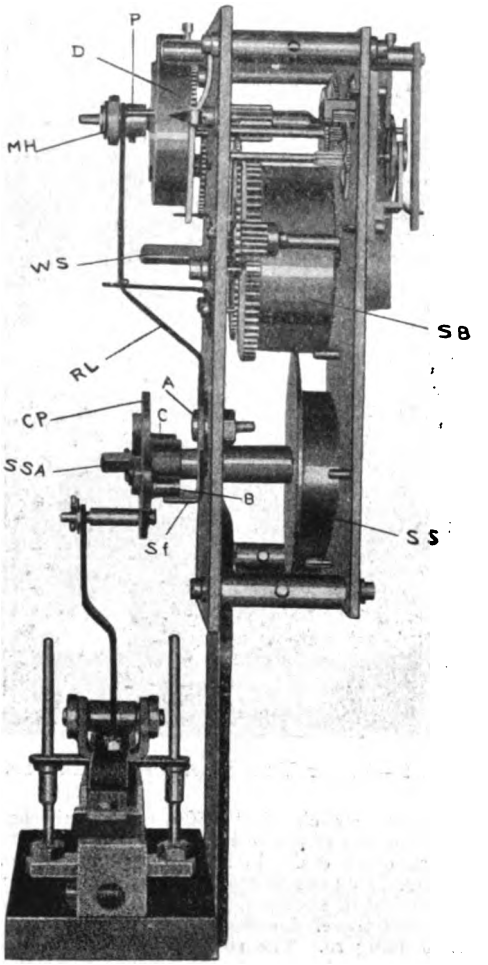

FIG. 1.—SIDE VIEW OF INTERIOR OF TIME SWITCH WITH COVER REMOVED.

actuating the switch is provided by a spring, which is quite distinct from the mainspring of the clock. There is sufficient power in the latter to keep the clock going accurately for fourteen days, and the switching spring is of ample strength to perform the operations of "quick-make" and "quick-break" once each per day during this period.

The mechanism of the clock is shown in Fig. 1. From the spring barrel S B movement is transmitted through the gear to the dials D D and minute hand M H. The dials take the place of an hour hand, and revolve once every twenty-four hours, the

Digitized by Google

minute hand, of course, making one complete revolution every hour.

The dials are in shape two flat pans, like the lids of circular tin canisters, and in the rim of each is a small slot (*S*, Fig. 2). These dials are a close fit on a collet on the clock arbor, and can be set in any desired position by hand for the switch to operate at any desired time. The release lever (*R L*) is the only connection between the controlling clock mechanism and the switching spring. It is pivotted at *A*, and carries at its upper end a pin (*P*) standing between the rims of the two dials and always resting against one of them. At the lower end of the release lever is a ledge or shelf (*Sf*), on one end of which is always resting one of the pins attached to the crank plate (*C P*) of the switching spring, and by reason of the lever being pivotted at *A*, it is thus kept always with the pin (*P*) at its top end touching one rim or the other of the dials. To the front of the crank plate is attached the crank pin, which provides the positive reciprocating motion necessary for the "quick-make" and "quick-break" of the switch.

The details of the switch itself are plainly shown in Fig. 2. A carbon break is provided in addition to the main laminated contacts.

Suppose that the switch is "on," and that the dials have been

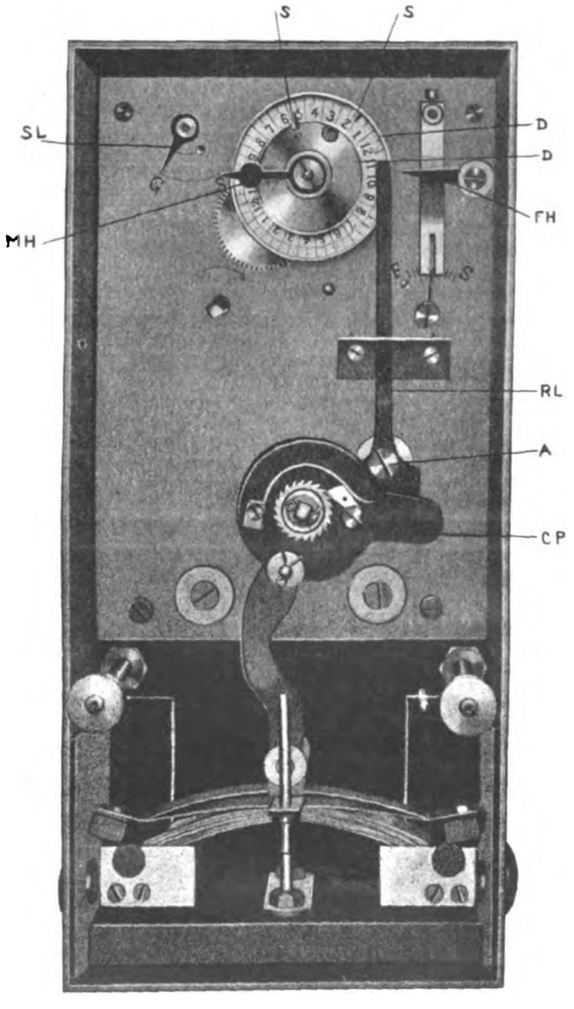

FIG. 2.—FRONT VIEW WITH COVER REMOVED.

set so that it will switch off at 1.30 a.m. It will be seen that the pin (*P*) at the top of the release lever (*R L*) is resting against the rim of the outer dial. It is held in this position because the pin *B* (Fig. 1) on the back of the crank plate is pulling on the right-hand end of the shelf (*Sf*) at the bottom of the release lever, and would travel downwards if the shelf were not there to prevent it doing so. The rim of the dial prevents the pin (*P*) from travelling downwards, but when the slot (*S*) comes opposite to the pin (*P*) (which it will do at 1.30 o'clock) there will no longer be anything to stop the pin (*P*) from moving. The top end of the release lever will, therefore, move to the right, consequently the shelf at the bottom will move to the left. This means that the pin *B* on the crank plate will be free to move downwards, allowing the plate to make a portion of a revolution. Therefore, the switch itself will be rapidly opened. Now there is another pin at the back of the crank plate, which is marked *C* in Fig. 1. When the plate starts rotating, this pin is carried round, and eventually fetches up against the left-hand end of the shelf. This, of course, stops any further rotation of the crank plate, and the switch is brought to rest in the "off" position. At the same time the top end of the release lever, which wants to travel to the left, is prevented from doing so indefinitely by the inner rim of the dials. It will be remembered that this inner rim is provided with a slot similarly to the outer rim. When this inner slot is brought opposite to the pin (*P*) by the action of the clock, the same series of events will take place, and the switch will be put on again. The pins *B* and *C*, of course, come into operation alternatively, and one or other must always be pulling on one of the two ends of the shelf of the release lever.

A SLIDING MOTOR CONNECTION BOX

THE accompanying illustrations represent a form of connection for motors which has been designed by Mr. E. Macgregor Duncan to obviate certain difficulties which are met with in the case where the leads must be entirely enclosed, although

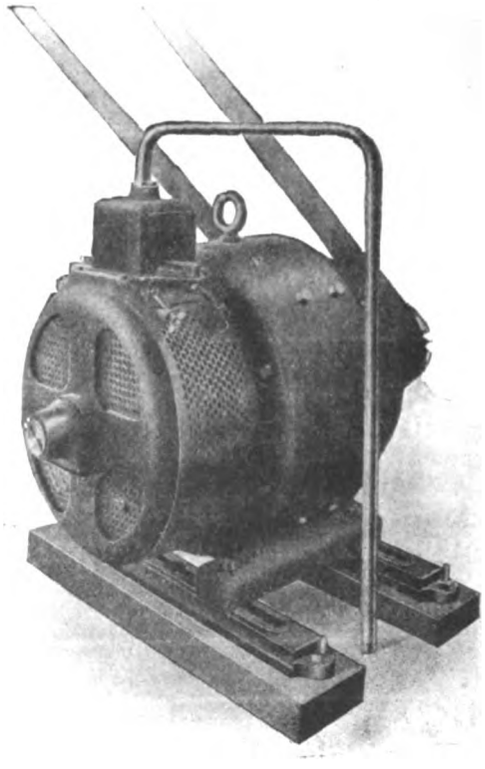

FIG. 1.—MOTOR FITTED WITH SLIDING TERMINAL BOX.

a certain degree of flexibility is required to permit of the motor being moved about upon its slide rails.

Figs. 1 and 2 show the apparatus in section and plan. The

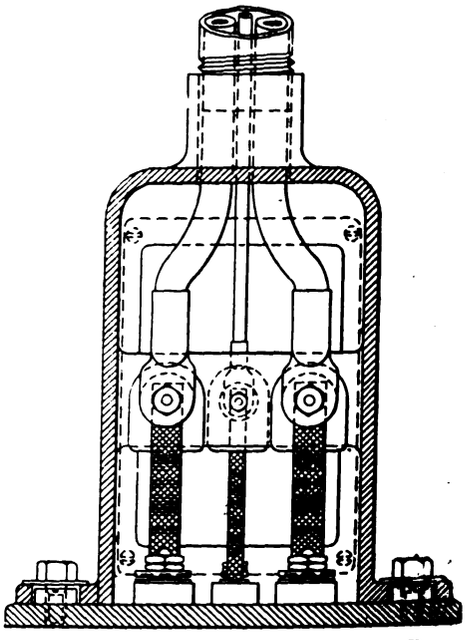

FIG. 2.—CROSS-SECTION OF TERMINAL BOX.

terminals of the machine are completely covered by means of a metal box, or cover, which is provided with slots at the side. These slots, which are kept in position by small blocks forming

Digitized by Google

part of the machine casing, allow the cover to slide either way relatively to the machine. The cover is provided with removable doors to make the inside accessible, together with a nozzle to which the tubing or conduit carrying the cables to the machine is screwed. The cover is provided with a cast rib bushed with insulating material to carry terminals, to which the cables are attached by means of thimbles. The cable terminals are connected to the machine terminals by means of flexible metallic conductors consisting of flexible braid or thin metal strips.

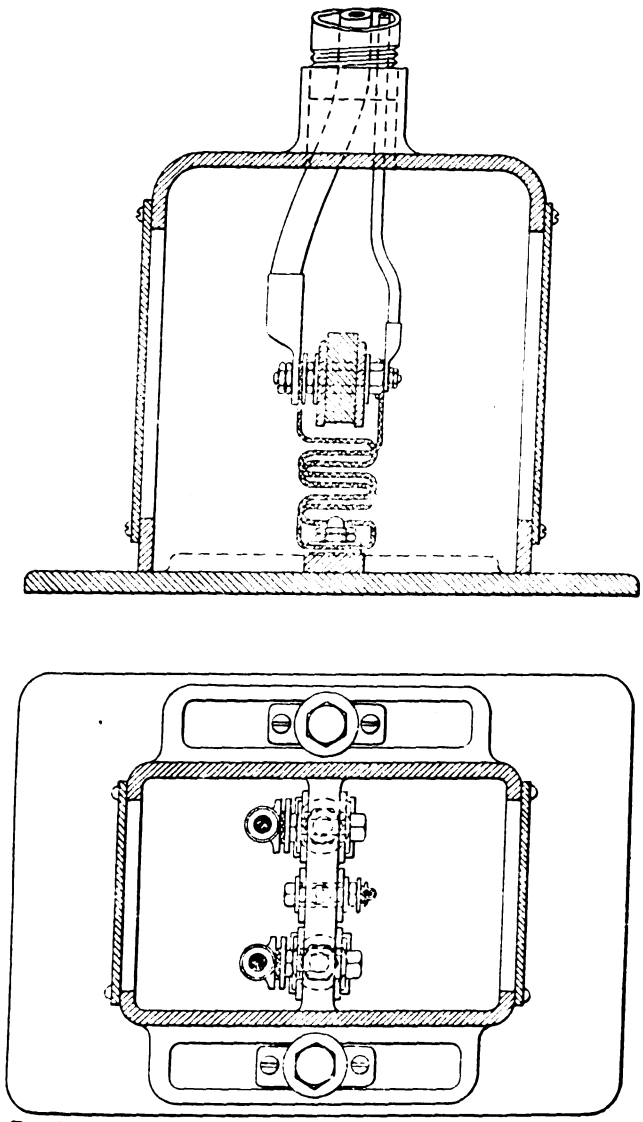

FIG. 3.—PLAN AND SECTION OF SLIDING MOTOR TERMINAL-BOX WITH FLEXIBLE CONNECTIONS.

As the conduit or tubing is fixed, it is only necessary to release the clamping screws, when the machine can be moved in either direction under the cover.

The machine will also be efficiently earthed through the screws if the conduit, or tubing, is properly earthed at some convenient point.

Fig. 1 shows a continuous-current motor fitted with the appliance as used on a number of machines in a large boot factory in the Midlands. A similar arrangement has also been adopted with success in the case of three-phase motors.

Queen's Engineering Works Magazine.—The current number of this magazine, which is published at the works of Messrs. W. H. Allen, Sons & Co., Ltd., Bedford, contains as a frontispiece a portrait of Mr. C. C. Hawkins, who has recently retired from the position of chief of the electrical department. Short accounts of the speeches made on the occasions of presentations from the firm, the staff, and shop employees respectively are given, together with some notes on Mr. Hawkins's career. A complete account of the annual distribution of prizes to pupils and apprentices, illustrated letters from past pupils engaged in work abroad, and other information of interest to past and present members of the firm are included, besides articles on steam turbines, engineering work in China, technical instruction at the works, and other subjects.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

ELECTRIC WELDING APPARATUS.—The new "Spot Welder" of the British Insulated & Helsby Cable Co. is described in a recently-issued pamphlet. This welding machine is designed for electrically-welding together sheet-iron plates or strips up to $\frac{1}{8}$ in. in thickness. The whole of the mechanism, with the transformer, is carried upon a substantial cast-iron base. The bottom stake or bracket can be clamped to the face plate in a great variety of positions in order to suit the particular work in hand. Both the electrodes are water-cooled and are fitted with interchangeable copper bits shaped to suit different work. The maximum power required during the welding period is less than 10 kw., and the total weight of the apparatus is only 670 lb.

ROTARY PUMPS, &c.—A pamphlet from the Albany Engineering Co., of Ossory Road, S.E., contains particulars of several patterns of the Albany rotary pump. The most important feature of these pumps is the fact that slip and leakage have been reduced to a minimum by the introduction of groove cuts along the faces and edges of the teeth, so that, in rotating, a body of water lodges in the grooves, forming an absolute sealed water-tight joint, or cushion, between the casing and rotating rollers, thereby producing an efficient vacuum. Centrifugal force, especially in the high-speed type, adds an immense amount of efficiency to the pump. The body is made of the best bronze with strong steel spindle running in long gun-metal bearings of ample area and accessibility for removal if necessary. A gear-box is fixed on side of pump containing two hardened steel spur wheels, which entirely eliminate wear from the internal members. Particulars of the firm's "Blizzard" propeller fan are also included.

HAULAGE GEAR & CRANES.—A new pamphlet, with some excellent illustrations showing a number of patterns of electrical haulage gears and cranes, is being issued by the Morley Electrical Engineering Co., Ltd., of Stanningley, Leeds. The firm, whose wide experience with this class of work is of great value in the design of machinery such as this, where reliability and good wearing quality under hard usage are essential, make their own motors and controllers specially for the purpose, although they are always ready to fit clients' own motors when desired. Special gas-tight designs to comply with rule 8 of the Coal Mines Regulation Act have been developed. The haulage gears illustrated cover a variety of forms, both fixed and portable, for underground and surface work. Another feature of the list is the series of hoists, transporters, and shop cranes for various requirements, and a complete system of overhead runways, the use of which is effectively shown in the illustrations.

DYNAMOS, MOTORS, &c.—We have received from the Conz Elektricitäts-Gesellschaft, of Hamburg, a series of lists of continuous-current dynamos and motors and alternating-current motors conveniently arranged in a cover. Each of the separate lists has the whole of the information given in English, German, and Spanish, and a very compact arrangement is obtained by keeping the three languages together on each page, as it is, of course, unnecessary to triplicate the tabular matter or the illustrations. The different sections of the list are as follows :—Continuous-current dynamos and accessories, steam dynamos, continuous-current motors for continuous running and for intermittent running, motor starters, and alternating-current motors, and this last section is further subdivided into parts dealing with three-phase induction motors for synchronous speeds of 1,500, 1,000, 750, 600, and 500 r.p.m. respectively on 50-cycle circuits, single-phase induction motors, and single-phase commutator motors. Any section is easily accessible by a thumb index at the side, and full technical information, dimensions, &c., are given in all cases. There are one or two interesting views of the shops in which these machines are made, and there is every evidence that the range of designs, besides being complete, is thoroughly up-to-date.

CALENDAR.—A monthly tear-off calendar is to hand from Messrs. Everett Edgcumbe & Co. Each sheet is embellished with a humorous application of a quotation from Shakespeare applied in an ingenious way to electrical measuring instruments, with a charming portrait of the great dramatist, by Mr. John Hassall, wearing an expression of astonishment at the interpretation placed upon his words.

TECHNICAL BOOKS.—We have received a catalogue from Messrs. H. K. Lewis, of 136 Gower Street, W.C., of new books and new editions recently added to their medical and scientific circulating library, which includes a number of works on electric science and engineering.

ELECTRICAL PLANT FOR MINES.—A very handsome and comprehensive illustrated new catalogue from Messrs. Ernest Scott & Mountain, of Gateshead-on-Tyne, describes this firm's standard specialities for electrical mining work, and shows in a striking way what a large range of electrical and applied machinery is manufactured by them. Several views of the works (which was described in ELECTRICAL ENGINEERING, Vol. IV., page 295) are given, and very numerous reproductions of photographs of electrical colliery plant, including power-house

Digitized by Google

equipment for steam-, gas-, oil-, and water-power; switch-gear for both under and above ground; pumping, haulage, and winding machinery of every variety; air compressors, capstans, and other plant driven by electric power. A most useful series of notes and tables of engineering information is also included, as well as an imposing list of colliery owners to whom Messrs. Ernest Scott & Mountain have supplied plant. We understand that at the moment the firm have in hand a large amount of work for Australia, including high-speed steam engines and three-phase generators, large and small three-phase and direct-current motors for mining and other work. They are also just completing for the Coltness Iron Co., in Scotland, an installation which comprises a 1,000-kw. alternator and two large three-phase motors of 450 h.p. each. For Young's Paraffin Light & Mineral Oil Co. they also have a complete pumping plant in hand for the Ingliston Mines, comprising a 400-h.p. steam engine, 300-kw. dynamo, three-throw pump delivering 600 gallons per minute, 600-ft. head complete with 155-h.p. electric motor and a similar pump delivering 500 gallons against 405-ft. head, complete with 85-h.p. motor, switchgear, driving ropes, cable, &c.

CORRESPONDENCE

WIRELESS TELEGRAPHY AT SEA.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read with much interest the note dealing with wireless telegraphy in your editorial columns this week. The unfortunate accident to the *Republic*, which cannot be said to have been entirely preventable with the present means at man's disposal, has served to rivet attention upon one of the benefits which wireless telegraphy has conferred upon the world, namely, the possibility of a ship's calling for assistance when in distress. This point has always been recognised as of primary importance by workers in this field.

Latterly, however, the installation of wireless telegraphy on ships has begun in many cases to be looked upon as a mere commercial affair, which, in return for a not very large but still considerable outlay, brings in receipts that either do not at all, or perhaps just do, cover the expenses, all considered, according as the installation happens to be on a less important ship or a liner with a record for something or other.

It is, however, possible for the friends of wireless telegraphy to argue from a new standpoint, whilst even the commercial folk may well reflect whether, having steamers which have cost large sums, and also passengers to think of, it is not worth their while to spend a few hundreds a year more on what may be regarded as a desirable insurance against dangers that are always threatening, but which now in many cases can be partially, if not entirely, avoided. As you have pointed out, it has already been proposed in America that a law should be passed making it compulsory for ocean-going passenger vessels to carry wireless outfits, but it appears to the writer that, whilst the results of such a law would be eminently desirable, it would be better first to convince the steamship companies that it would be to their interest and profit in the long run to equip their ships in this manner. If they then acted on the initiative no compulsion would be needed; but should considerations of individual gain still remain uppermost, it would be easy later on to devise some effective form of legislation. Coming now to the technical side, it must be conceded that, all things considered, the arrangements for distress signals worked fairly well. One of your contemporaries has, I notice, entered a plea that "similar apparatus" should be employed on all ships, but this has proved quite unnecessary. It does not, however, appear to have been recognised that one reason why help was so effectively rendered in this case was due to the fact that the vessel was an Atlantic liner following a definite course. Several of the answering ships were of the same class; and, knowing the course and probable position, it was comparatively easy to steam within range of the *Republic's* submarine bells.

How different, however, might have been the case had the steamer in distress only been able to send out the actual distress signals before her wireless apparatus became unworkable, or even had the vessel in distress been pursuing one of the less well-known routes, or had no definite course! Then, again, another ship might not be fitted with submarine signalling apparatus. The delay incidental to ascertaining the position of the ship in distress, and even after that in eventually locating her, is all time, which might prove of incalculable importance to the hapless vessel or her living freight.

It appears to the writer that while wireless telegraphy *per se* is belauded as having accomplished so much in the cause of humanity, only two of the writers in the technical or the lay Press appear to have grasped the fact that the most important and necessary information required before it is possible to proceed to the assistance of a ship in distress is the knowledge of its *direction*.

Although it has for some time been recognised in scientific circles that there already exists one simple, practical, and effective means of determining, almost instantly, the direction of any wireless telegraph station sending signals, this method does not appear to be generally known, nor its potential value to have been realised; but a practical example of its usefulness, such as the present case leads one to perceive, should do much in the way of enlightenment.

The directive method of Bellini and Tosi has, for instance, received but scant notice in the lay Press, perhaps owing to its very simplicity.

The method itself has been fully described in your columns, and so need not be detailed here; but emphasis may be laid upon the extreme flexibility of the arrangements, in that it is possible, so to say, to combine three systems in one, and to rapidly change over from one to the other. First, the ordinary circular radiation method, which is of special value for intercommunication and for distress signals. Second and third, the directive arrangements, which can be resorted to as soon as the first call is heard; on getting the signals on the directive apparatus, the direction of the calling ship or station is at once known without requiring any actual message.

Whilst it may not in every case be possible, or convenient, to instal a directive equipment on board ship, there is no doubt that the provision of such directive apparatus in land stations situated at certain important points, such as New York or Boston, for instance, is of vital importance, and would contribute in no small degree to the security of the ever-increasing army of ocean travellers, and of the brave crews in the ships which carry them.

In conclusion if, as is now admitted, wireless telegraphy is such a boon, is it not imperative that a method should be adopted which gives the most information as to whereabouts in the least time? The Bellini-Tosi directive system, which can be adapted for use with any existing system, does this upon the mere receipt of just a few of the now officially recognised - - - — — — - - - signals.

I am, Sir,
Yours, &c.,
L. H. WALTER.

Westminster, S.W., January 30th, 1909.

SURFACE-CONTACT SYSTEMS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—I have read with great interest the report in your columns of Mr. Clegg's Paper on the G.B. System at Lincoln, and ask space to express the hope that the genius will soon arise to overcome, by the simplicity of his inventions, the difficulties which, for lack of the right inventive faculty, at present encumber the whole question of surface-contact traction.

What is wanted is a system which possesses the following advantages :—

1. It must be of such simplicity that nature does her own work.
2. It must be encumbered with no springs or exotic embroideries, but must depend on a pull-off working by gravity alone.
3. It should be inexpensive to lay down, and should show the minimum loss of current. It should not require an excavation of more than six inches.
4. Such a thing as a live stud should be not only theoretically impossible, but safeguards should be introduced to operate in the event of the unexpected happening. These should provide that (*a*) the stud should be hermetically sealed against moisture, &c., and so arranged that the current would be earthed the moment anything unforeseen made the stud alive; and (*b*) in order to overcome the contingency of the action of gravity being interfered with, such as through the setting up of permanent magnetism, the operating magnet should be supplemented by a repulsive magnet.

These are severe conditions, but they are essential, and I am sure that there is sufficient inventive ability in the world to fill them.

I am, your obedient servant,
Fowey, January 23rd, 1909. A. WADDELL.

Obituary.—We regret to record the death of Mr. W. W. Strode, of Messrs. Strode & Co., 48 Osnaburgh Street, London, N.W., which occurred after a few hours' illness on Saturday morning as the result of cerebral hæmorrhage, brought about by a stumble as he was on his way to the railway station. Mr. Strode, who was the third generation of the firm of Messrs. Strode & Co., was educated at Brighton College, in Germany, and in France. Taking an active part in the business of the firm for forty years, he had carried out a very large number of electric lighting, heating, and ventilating contracts, in addition to a good deal of work with gas. He was a strong advocate of the steel conduit system of wiring, and was a member of the Electrical Contractors' Association. Mr. Strode was 58 years of age.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A complete power equipment, comprising two steam-driven 200-kw. 3,000-volt three-phase alternators, condensing plant, boilers, pipework, and switchboards, has recently been installed by Messrs. W. H. Allen, Son & Co., of Bedford, in the generating station for the supply of Khartoum. (Page 130.)

Although it is not expected that electric trains will be running in the public service on the South London line for some months to come, trial runs have already taken place on the section of the line between Battersea and East Brixton. We give some details of the new rolling stock and of the electrical equipment, together with some notes as to the extent of the progress made in the electrical equipment of the line. (Page 132.)

In a Paper read before the Faraday Society on Tuesday, Dr. S. Rideal described improved forms of apparatus used in the application of electrolytic chlorine to sewage purification and deodorisation. Experiments showing how rapidly chlorine in the form of hypochlorites will deodorise the sewage effluent were also described. Under "Electrometallurgy and Electrochemistry" we also give some particulars of a new process for the manufacture of aluminium carbide. It has been suggested to coat iron electrolytically with lead before galvanising as a further protection against rust. (Page 134.)

Dr. C. V. Drysdale suggests an application of a phase-shifting transformer to enable the potentiometer to be employed for A.C. measurements. (Page 134.)

The Tariff Commission has issued Vol. IV. of its reports, which deals with the electrical and engineering industries. Evidence is given by a number of electrical manufacturing firms, and statements are also published from a large number of others, the burden of which is that protective tariffs should be imposed in order to prevent the dumping of foreign goods into Great Britain. Strong protest is made against the action of many municipalities which have given orders for electrical machinery to Continental firms. (Page 135.)

At a recent meeting of the Physical Society, Dr. A. Russell read a Paper in which he gave a solution of

Digitized by Google

the problem of the effective resistance and inductance of a concentric main. Several interesting points in connection with telephone cables were brought out in the discussion which followed. (Page 136.)

IN connection with a recent article in these columns on the competition between electric power and suction-gas plant, a correspondent quotes some low costs obtained with a gas-driven generating plant. Mr. G. L. Addenbrooke draws attention to some inaccuracies in our report of his third Cantor lecture. Other letters refer to the Eclipse boiler furnace, and the use of wireless telegraphy at sea. (Page 137.)

IN a lecture before the Bradford Engineering Society last week, Mr. A. W. Bennis gave complete descriptions of the various forms of mechanical stokers now on the market, and pointed out the most recent developments in their construction. (Page 138.)

AMONG the patent specifications published by the Patent Office on Thursday last was one by H. Herrenschmidt for an improved process for the electrolytic extraction of aluminium from bauxite. A combined switch and fuse, in which the switch is automatically opened when the fuse melts, is described in a specification by J. A. Kennedy-McGregor and H. H. Mountford, and another by A. D. Jones relates to the magnetic control of the arc in enclosed flame arc lamps of the vertical carbon pattern. A specification by W. Fennell and W. P. Perry describes an improved form of the "flicker" photometer, in which the reflecting surfaces are replaced by a translucent disc. The British Thomson-Houston Co. have patented a method of applying an additional resilient support to the filaments of metal filament lamps, and a device for limiting the speed of telephone magnetos has been patented by G. Buschelberger. The only patent of electrical interest which expires this week after its full term of life relates to a keyboard for the automatic telegraphic transmission of the Morse signal corresponding to the letter represented by the key depressed. Short abstracts of the above specifications and a classified list of the specifications published to-day are given in our Patent Record. We also give a classified list of the more important patents that have expired through non-payment of renewal fees. A lapsed patent, relating to the ventilation of electrical machinery, and granted to H. Chitty, has been restored. (Page 139.)

AN interesting case is being heard at the Thames Police Court, in which it is to be determined whether the term "Trinidad bitumen" implies only natural bitumen as obtained from the bitumen lake in Trinidad and the land surrounding it, or whether it is also a correct designation for a mixture in which "manjak," mined in Trinidad and consisting of almost pure bitumen, is one of the chief constituents. (Page 140.)

SOME useful fittings for shop lighting have recently been introduced. We also describe a new combined knife switch and fuse. (Page 142.)

THE Comptroller-General of Patents has decided that patent number 18,786 of 1902, for the Bremer flame arc lamp, shall be revoked owing to lamps under the patent not having been manufactured in this country to an adequate extent. The owners of the patent are the Westinghouse Co., and the Union Electric Co. are licensees. The case was heard on the petition of Mr. G. Braulik. The decision will be subject to appeal to the High Court. Similar proceedings are being taken against patent 23,606 of 1902, owned by the firm of Körting & Mathiesen, who manufacture the "Excello" lamp, and whose agents in this country are the Union Electric Co. (Page 143.)

THE Bath Corporation has accepted the recommendation of the Electricity Committee to break off negotiations with Mr. Schenk for the sale of their electricity undertaking.—As the result of Mr. Hamilton's report upon the Bournemouth tramways undertaking and the recommendations of a sub-committee, the traffic manager and the electrical engineer have resigned.—The East Ham Corporation has agreed to the West Ham Corporation giving a supply in their district to a consumer not reached by the East Ham mains.—The Folkestone Corporation are insisting upon the question of the tramway system to be adopted by the National Electric Construction Co. being determined by arbitration.—The Highways Committee of the London County Council recommend the purchase of a portion of the Harrow Road and Paddington tramways at £40,000.—A petition has been deposited by the Oxford Corporation against the Bill of the National Electric Construction Co. in order to prevent the adoption of the overhead system.—There is a deficit of £856 upon the working of the Walsall electricity works for last year.—Special supplemental mechanical attachments are to be fitted to the magnetic brakes upon the L.C.C. tramcars. (Page 144.)

A SCHEME of electricity extensions at Bradford costing £50,000 has been adjourned for a month. Some 300-kw. motor alternators are required at Cardiff; a water-tube boiler, &c., at Ashton-under-Lyne; condensing plant at St. Helens, and pumping plant at Salford. The Stepney Council propose to borrow £7,860 for house services, &c. (Page 147.)

THE accounts of the Baker Street and Waterloo Railway, Great Northern, Piccadilly and Brompton, and Charing Cross, Euston, and Hampstead Railway, for the December half-year, show very considerable increases in the receipts, and the two former declare dividends on the ordinary shares. The City Undertaking of the Charing Cross, West End, and City Electricity Supply Co. for 1908 show a net revenue of £23,110, and the West End undertaking of £43,163. A dividend of 5 per cent. is declared upon the ordinary shares of the latter.—After payment of mortgage interest there is a balance of £717 on the working of the Yorkshire Electric Power Co. for 1908, compared with the loss of £1,350 for the previous year.—There is a balance of £11,613 shown in the accounts of the Metropolitan District Railway Co. for the past half-year, and a dividend of £1 15s. per cent. is declared upon the 4 per cent. guaranteed stock.—A 10 per cent. dividend is declared on the ordinary shares of the St. James & Pall Mall Electric Light Co. for 1908. (Page 148.)

THE Comptroller-General of Patents has just announced his decision revoking the Bremer flame arc lamp patent, under Section 27 of the Patents Act of 1907, on the ground that the lamp patented is not manufactured to an adequate extent in this country. The patent in question is owned by the Westinghouse Co., and the Union Electric Co. are licensees, so that the decision—if upheld by the High Court, for of course there will be an appeal—will affect the position both of the Westinghouse and the "Excello" flame arc lamps. The same "petitioner," Mr. George Braulik, who has been instrumental in obtaining this decision, is petitioning in a similar manner against the Högner patent, which is owned by Messrs. Körting & Mathiesen, and is the other fundamental patent under which the "Excello" lamp is manufactured by the above firm and sold in this country by the Union Electric Co. The result in this second case is not yet announced. In addition to the extreme importance which attaches to the revocation of the Bremer arc lamp patent, the decision is interesting for two other reasons. First, it appears that lamps have actually been manufactured under the patent in this country at the Westinghouse

Digitized by Google

works, and that this is the first decision on the meaning of the word "adequate" in the new Patents Act. Secondly, it is to be noticed that the petitioning firm is not itself actually manufacturing, and that the first result, at any rate, will be a freer importation of arc lamps into this country, rather than an improvement in the position of the British manufacturer.

It will be noticed that we have introduced a new feature in our Patent Record this week, namely, the addition of a list of the more important British patents whose allotted life of fourteen years has been cut short through non-payment of fees. It is probable that the number and importance of such patents will gradually increase as a result of the revocation clause in the new Patents Act. At present, if a British patent which is worked abroad and not in this country is revoked under this clause, the owner of the patent has not only to suffer by the fact being widely commented on in the Press, but he is also liable to pay the costs of the proceedings before the Comptroller in connection with the necessary petition and inquiry, whether he has defended his case or not. Obviously, if he does not propose to work his patent in this country, he will be better advised to let the patent lapse previously, through an omission to pay the renewal fees upon it. There are other reasons why patents, seemingly of practical value, are allowed to lapse after a life of five or six years or more, and we have no doubt that the list which we are now publishing from week to week will be of some considerable interest to many of our readers.

The Bath Corporation has now definitely decided to break off the negotiations for the sale of their electricity undertaking to a company. These negotiations had been going on for two years with Mr. Schenk, who was acting on behalf of the Bath and District Electricity Supply Co., and indirectly for the Somerset and District Electric Power Co. The result is a timely reminder of the powers of the Board of Trade in such matters. It is entirely due to the firm attitude taken up by the Board that the Bath Corporation have decided to abandon its attempt to rid itself of an undertaking which has been none too successful; the only alternative for the Corporation would have been an expensive fight with this Government Department before a Parliamentary Committee. The Board has refused its sanction to the transfer for certain definite reasons, the main one of which is that there is no authority under the Electric Lighting Acts for a municipality to lease their undertaking in perpetuity. It is truly remarkable that neither party should have informed themselves on this point at an earlier stage. Another objection raised by the Board of Trade was that the Corporation would have been making a profit on the transaction, in addition to getting full price for plant many years old. In this, of course, the Board was apprehensive on behalf of the consumers of the company, for a transfer to a company of an undertaking now run at a loss, with a simultaneous increase in the capital account, must, in the first instance at any rate, point to an increased charge for electricity supply. On the other hand, the Board has sanctioned many a transfer from a company to a local authority with a substantial profit; but presumably the Board in such a case considers that the interests of the consumers will be better safeguarded, as they are then, so to speak, part owners of the undertaking. Yet the Bath Corporation can hardly be blamed for being willing to accept a sum from the company which would enable them to pay back in the form of relief of rates sums which have been in past years paid out of the rates to make good deficits. These are some of the anomalies from which municipal trading is bound to suffer.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 11th.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, S.W. Paper to be read :—"Use of Large Gas Engines for Generating Power," by L. Andrews and R. Porter.

Institution of Electrical Engineers: Dublin Local Section.

8 p.m. Meeting at the Royal College of Science for simultaneous discussion of the above Paper.

FRIDAY, FEBRUARY 12th.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, St. John Street, Clerkenwell. Paper to be read :—"A Modern Winding Engine," by E. A. Smart.

Physical Society.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute Road, when the Presidential Address will be delivered.

SATURDAY, FEBRUARY 13th.

Electrical Football League.

3 p.m. The following matches will be played to-day :—St. Pancras Electric v. Ediswan, at Swain's Lane, Highgate; County of London v. St. James' Electric, at the Guards' Polo Ground, Southfields, S.W.

Finsbury Technical College Old Students' Association.

6.30 p.m. Third annual dance at Caxton Hall, Westminster.

Signal Engineering Society.

7.30 p.m. Meeting at the Mansion House Station Restaurant, E.C Paper to be read :—"The Board of Trade Requirements for Railways," by H. Raynor Wilson.

Association of Engineers-in-Charge.

7.30 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street, London, when Mr. J. B. Kershaw's Paper on "Feed Water and its Impurities" will be further discussed.

MONDAY, FEBRUARY 15th.

Royal Society of Arts.

8 p.m. Cantor Lecture I., "Modern Methods of Artificial Illumination," by L. Gaster.

TUESDAY, FEBRUARY 16th.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting at the University, when the Paper by Messrs. Andrews and Porter on "Use of Large Gas Engines for Generating Power," will be discussed.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal Technical School. Paper to be read :—"The Utilisation of Exhaust Steam for Electric Driving," by C. S. Richards.

WEDNESDAY, FEBRUARY 17th.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. Meeting at 92 Victoria Street, Westminster, London. Paper to be read :—"Purification of Boiler Feed Water," by Thomas Walmsley.

THURSDAY, FEBRUARY 18th.

Institution of Electrical Engineers: Students' Section.

7 for 7.30 p.m. Annual dinner at the Holborn Restaurant, London.

Extension of Electrobus Service.—The London Electrobus Co. announced last week that their Liverpool Street to Victoria route would be extended to Earl's Court, through the following thoroughfares :—Ebury Street, Sloane Square, Sloane Street, Brompton Road, Cromwell Road, Earl's Court. This extension of route will not, they add, in any way change the system of fares which has been usual with this company.

ELECTRIC POWER SUPPLY AT KHARTOUM

AMONG the features of the modernisation of the town of Khartoum is a large electric power station, for which Messrs. W. H. Allen, Son & Co., Ltd., of Queen's Engineering Works, Bedford, have recently supplied a quantity of plant to the specification of Captain Kennedy, R.E., of the Sudan Government.

The boilers are of the "Economic" type, and have been constructed by Davey, Paxman & Co., of Colchester. Each of the two boilers which have been put down is capable of evaporating 6,000 pounds of water per hour at a pressure of 165 pounds per square inch, and a superheater is placed in the combustion chamber

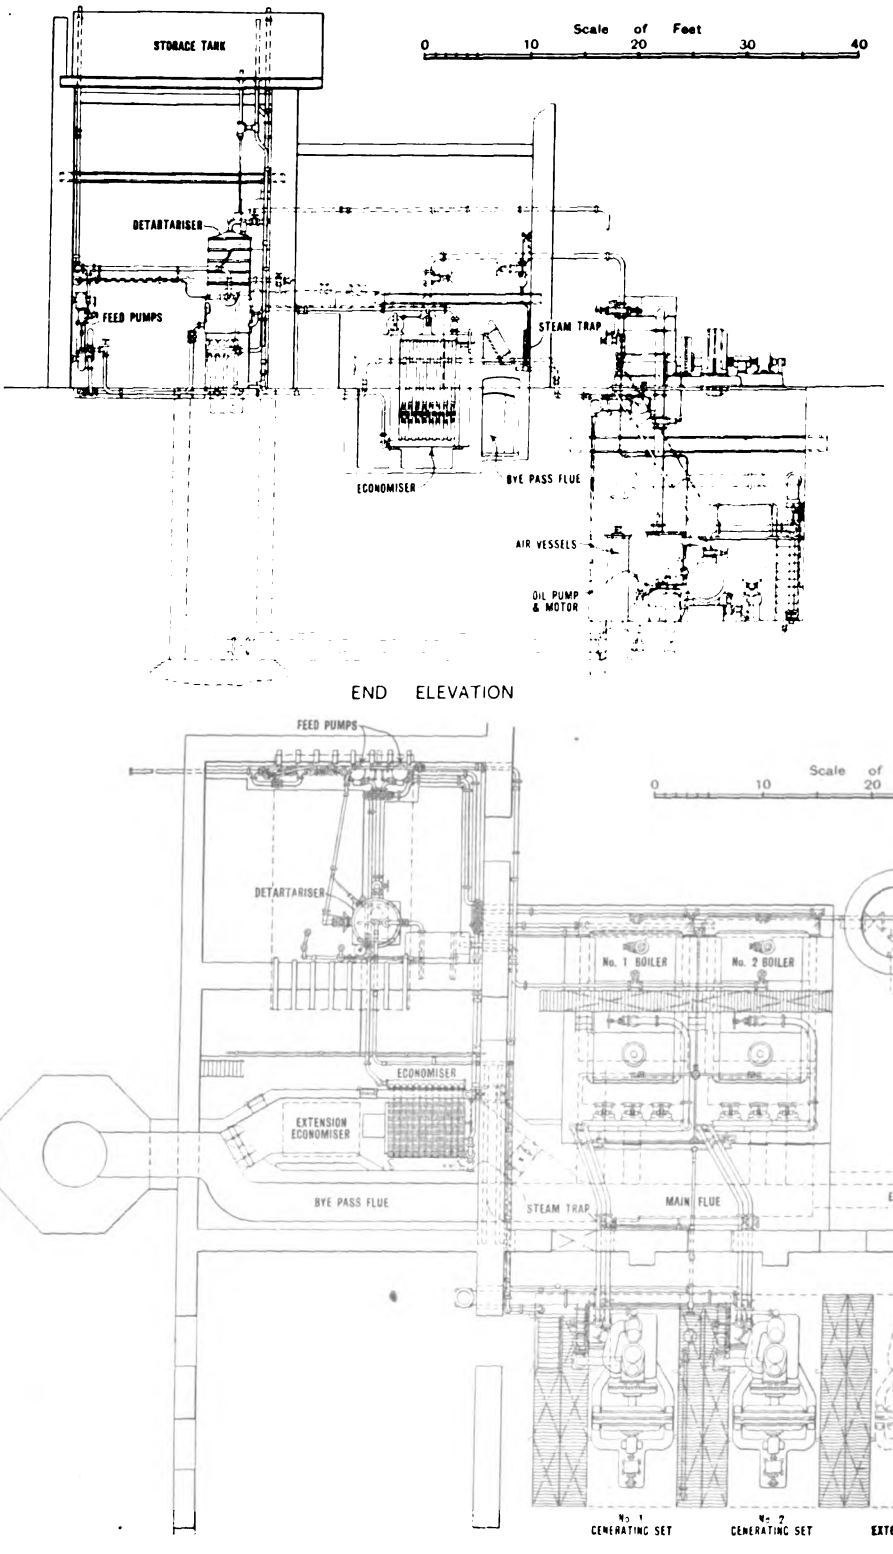

FIG. 1.—END ELEVATION AND PLAN OF KHARTOUM POWER STATION.

The contract comprised boilers, superheaters, economiser, engines and alternators, condensing plants, high- and low-tension switchboards, pipework, &c., and the arrangement embodies a number of points of interest. The section and plan in Fig. 1 show the general disposition of the equipment of the station, and Figs. 2 and 3 give views of the more important items.

at the back end of each. The superheaters have a sufficient area of heating surface to enable them to impart to the full output of the boilers 150 degrees Fahrenheit of superheat when the boilers are working at their full pressure. The economiser is of Messrs. E. Green & Sons' manufacture. It is arranged in 12 sections of eight tubes, making 96 in all. Each of the

Digitized by Google

tubes in the economiser is fitted with a patent triple scraper, and these scrapers are driven by an electric motor in the usual way.

pound pattern, having cylinders 12 in. and 21 in. diameter by 9 in. stroke, and are coupled directly to three-phase alternators. Each set gives a full load

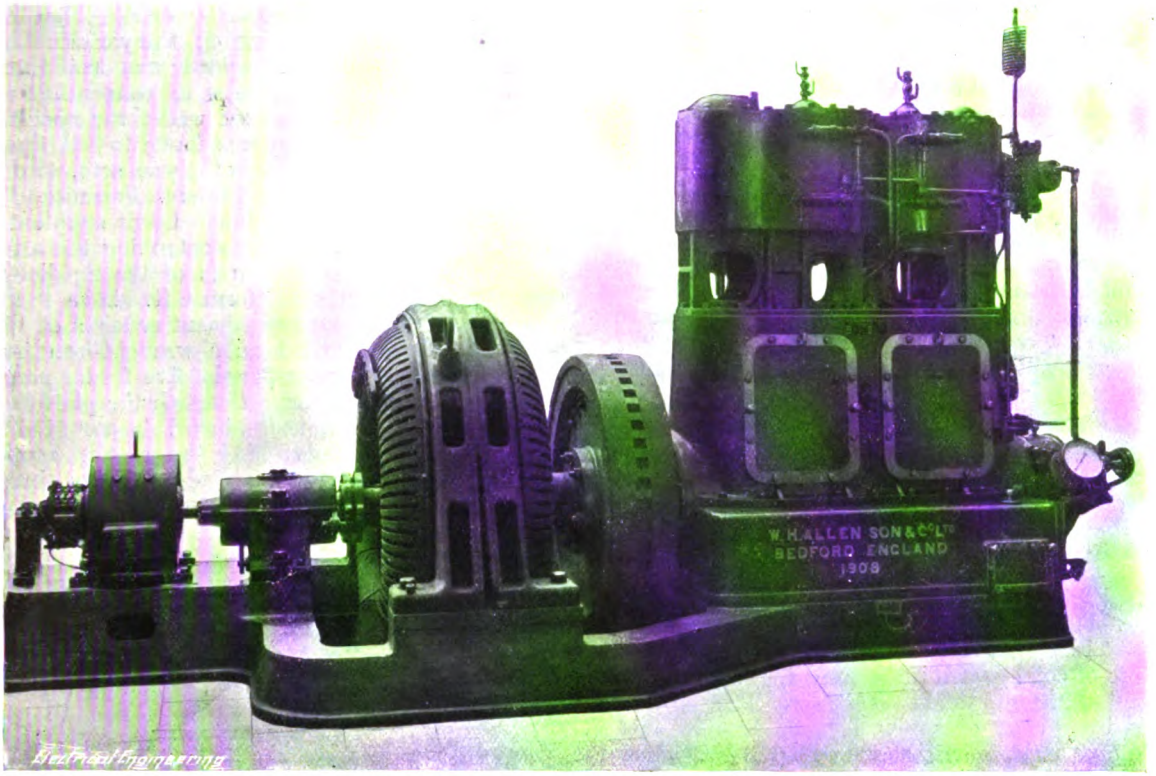

Fig. 2.—Allen-Crompton 200-kw. High-speed Set.

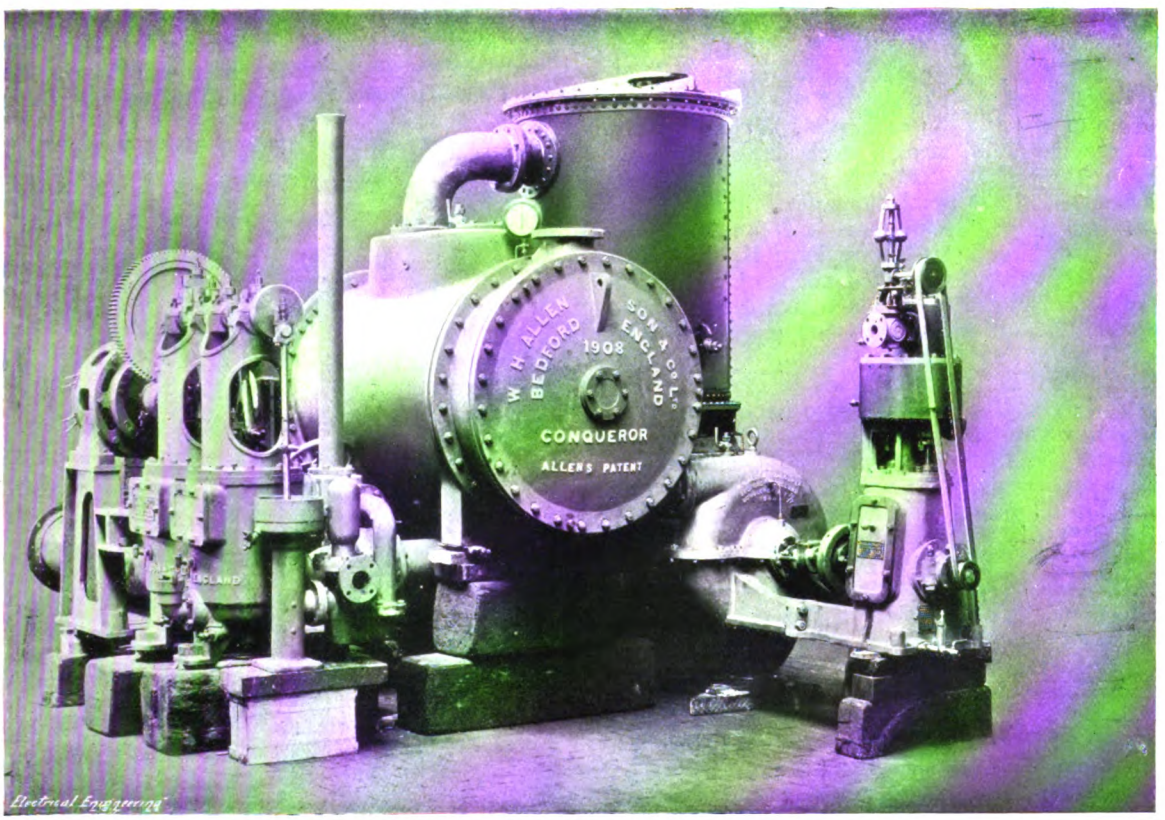

Fig. 3.—Allen Surface Condenser and Pumps.

Two generating sets have been put down, but space is left to accommodate extensions. The engines are of Messrs. W. H. Allen, Son & Co.'s standard high-speed two-crank two-cylinder vertical enclosed com-

output of 200 kw. at 3,000 volts, with a power factor of 0·85, at a speed of 428 revolutions per minute, and is also capable of giving an overload of 15 per cent. when running under these conditions. Direct coupled

Digitized by Google

shunt-wound exciters are provided, each of which is rated at 25 kw.

The alternators are of the ordinary three-phase type, with revolving fields and stationary mesh connected armatures, manufactured by Messrs. Crompton & Co., Ltd., of Chelmsford. One of the sets is shown complete in Fig. 2.

Two 25-kw. transformers of the enclosed ventilated core type have also been provided. The primary winding of these is wound for a working pressure of 3,000 volts between the phases, while the secondary winding is wound to give a pressure of 230 volts. A metallic earthed screen has been supplied between the primary and the secondary winding.

To deal with the exhaust steam from the engines and generators, two surface condensing plants have been supplied, and these are placed in the basement immediately below the respective generating sets, as shown in Fig. 1. A view of one of these condensers complete with its pumps is shown in Fig. 3. Each condenser has a tube surface of 700 sq. ft., and deals with 6,000 lb. of steam per hour when supplied with circulating water at a temperature of 85° F., and is capable of dealing continuously with 15 per cent. overload. The condensing plant will produce a vacuum of 3 in. within the barometric pressure.

The condenser shell is circular in form. The end covers are removable without breaking any pipe joint, and are fitted with hand holes for the purposes of inspection and cleaning. The tube plates are of the best rolled brass, 1 in. thick, and are thoroughly well tinned. The tubes are of solid drawn brass tinned, $\frac{3}{4}$ in. external diameter and 0·048 in. thick. They are fixed in the tube plates by means of screwed brass ferrules and tape packing at both ends. The ferrules are provided with lips to prevent their slipping out of place. A baffle plate is provided in one water head, and is so arranged that the water passes first through the lower half of the tubes and thence through the upper half of the condenser, discharging through the outlet at the top of the condenser. Diaphragms are also provided to ensure an efficient distribution of the steam. The air pumps are of the two-throw design, having barrels 10 in. diameter by 7 in. stroke, each driven through gearing by a three-phase 220-volt motor, the latter running at a speed of 575 revolutions per minute. The speed of the air pumps themselves is 135 revolutions per minute. The circulating pump is of the high lift turbine character, and delivers 665 gallons of water per minute against a head of 40 ft., inclusive of pipe friction, when running at a speed of 500 r.p.m., and is driven direct by an engine having cylinders 6 in. and 8 in. diameter by 3 in. stroke. Each engine develops 13 b.h.p. A hot well pump has also been provided, which is connected to the discharge from the air pump and is driven off the air-pump crank shaft. This pump delivers its water against a head of 30 ft. The discharge from the oil pump is collected in a galvanised iron closed tank.

A complete system of pipework has been supplied, together with the necessary steam traps, fire and hydrant pipes, &c. This portion of the contract also includes two feed pumps, each of which delivers 4,000 gallons of water into the boilers against a pressure of 165 lb. per square inch. These pumps are capable of working with either cold water or with water having a temperature of 210° F. The water, before being delivered into the boilers, is softened by a detartariser. This is capable of heating the water to a temperature of 212° F., and of softening 660 gallons of water per hour.

The engines and dynamos were tested at Messrs. W. H. Allen, Son & Co.'s works, and the following steam consumptions were obtained, the steam pressure being 160 lb. per square inch, and the results based on a superheat of 130° Fahr. :—

Full load, condensing	22·7 lb. per kw.-hour	
Full load, non-condensing ...	26·9	,, ,,
$\frac{3}{4}$-load, condensing	23·6	,, ,,
$\frac{3}{4}$-load, non-condensing	29·0	,, ,,
$\frac{1}{2}$-load, condensing	26·3	,, ,,
$\frac{1}{2}$-load, non-condensing	33·9	,, ,,

With regard to the governing, the variation in steady speed between full and no-load was less than 2 per cent. The circulating pumps in connection with the condensing plant were tested under the specified conditions, and the efficiency was found to be 73 per cent.

To deal with the outfit of these sets, two switchboards, manufactured by Messrs. Ferranti, Ltd., of Hollinwood, Lancashire, have been supplied. The high-tension switchboard for controlling the alternators and the distributing system is of the flat-board type, and is mounted on a platform 6 ft. above the engine-room level. The board at present consists of 11 panels of white marble carried on a wrought-iron frame, of which five are generator panels, five feeder panels, and one a main output panel. Beneath the platform carrying the high-tension switchboard is mounted a low-tension board for controlling the station motors and lighting. This board is supplied from two three-phase transformers mounted behind the high-tension switchboard, and it consists of three white marble panels carried in a wrought-iron frame. The board carries two main triple-pole fuses for receiving the current from the two transformers, and eight triple-pole fuses and eight ammeters for the circuits.

We are indebted to Messrs. W. H. Allen, Son & Co., Ltd., for the above particulars, including the drawings and photographs.

ELECTRIFICATION OF THE SOUTH LONDON RAILWAY

ALTHOUGH the electrical equipment of the South London line is not yet complete, trial runs have already been made on the section between Battersea and East Brixton, and, we understand, have given

END OF MOTOR-COACH, SHOWING MOTORMAN'S AND GUARD'S COMPARTMENTS AND THE BOW COLLECTOR.

every satisfaction. The following particulars of the line, which extends from Victoria to London Bridge, *viâ* Battersea, East Brixton, Peckham Rye, &c., and

Digitized by Google

has a route length of nearly nine miles and a track length of approximately 23 miles, are to hand.

Inside Victoria Station seven lines will be equipped with overhead construction, giving access to five platforms, and in London Bridge Station five platforms will be fitted. The time at present taken for steam trains from Victoria to London Bridge is 36 minutes; electric traction will reduce this to 25 minutes, and it is intended to run a 10 minutes' service. At the present moment the section from Battersea to Peckham Rye is nearly completed, and test runs will shortly be made upon it to verify the contractors' guarantees. The repair shops and car sheds are now under construction near Peckham Rye. Here the trains not in service will be kept, and the equipment examined. To these shops will also be transferred the telegraph, telephone, and other electrical repair sheds now at New Cross. It is expected that as soon as the repair-shops are completed the whole of the equipment from Victoria to London Bridge will have been carried out; the Brighton Railway Company will then be in a position to commence running for the public electrically between these termini in both directions. This may be in June next.

The repair-shops at Peckham Rye are in telephonic communication with the switch cabins, which are situated at, or near, each of the stations, and from which the operation of the whole line can be controlled. The apparatus accessible is entirely on the low tension side, which obviates any risks in operating. The repair-shops at Peckham Rye are also in telephonic communication with all the signal cabins. The current for operating the trains is obtained from the London Electrical Supply Corporation, whose mains from their station at Deptford to the switch cabin at Queen's Road Station have already been laid and tested, and whose railway generating plant, consisting of four units of some 2,000 kw. each, has been installed and is in readiness at Deptford to supply the requisite power. The switch cabins at Queen's Road contain the meters which register the amounts consumed. From here duplicate feeder cables are taken to the Denmark Hill switch cabin, which is the principal cabin on the line, and contains the various recording instruments required by the Board of Trade; these are practically the same as those obtaining in the case of tramways.

As is well known, the system of electric traction adopted is the single-phase alternating-current high tension one. In consequence of the high pressure (6,700 volts), only 100 or 140 amperes are required per train, and the circuit-breaker in no case need be set at much over 500 or 600 amperes. All the high-tension apparatus on the trains is enclosed in fireproof steel compartments, and access to it can only be obtained after the current is cut off and the whole apparatus connected to earth. All the circuits for lighting and control, and in fact every circuit to which it is possible to obtain access whilst current is on, in no case exceeds a pressure of 300 volts.

Current is collected from an overhead ½ in. diameter wire, which is supported at intervals of about every 10 ft. from two stranded steel cables, by a collector bow, fixed on the roof of the coach as shown in the illustration opposite. The contact strips of these bows are composed of aluminium, fitted with grooves filled with heavy grease. The upward pressure against the wire amounts to very little, so that the wear on the copper contact wire is not appreciable, the whole wear practically taking place on the aluminium strip which can be easily and cheaply renewed. The current from the bow is taken into the high-tension chamber, where are located the various safety devices, and is then conducted in lead-covered cables laid in metal casing to the two transformers situated under each motor-car; from here low pressure current is taken for the motors and for the controlling apparatus.

The rolling stock at present constructed consists of eight trains; each train is made up of three coaches, the first and last being a third-class carriage fitted at one end with the guard's van and motorman's compartment. The centre coach is not equipped electrically, and is entirely devoted to first-class passengers; there are only first- and third-class coaches. The two end coaches are motor coaches, and each is fitted with four 120-h.p. Winter-Eichberg compensated repulsion motors. All the coaches are provided with side doors. Each third-class coach has eight passenger compartments, in which a normal accommodation is provided for seating 66 passengers. The first-class coach comprises 9 compartments, and normally seats 56 passengers. In order to provide for even distribution of passengers, a gangway has been provided; these passage-ways are so arranged that on one-half of the carriage they are situated on one side, and on the other half on the opposite side.

The lighting of the trains is provided by a double circuit of lights, each compartment being fitted with two Holophane globes, containing two 10-c.p. lamps, or 40 c.p. to each compartment. Each coach is fitted with two chemical fire-extinguishers and with two oil lamps, so situated as to be easily accessible to the passengers or to the guard in case of emergency. Every precaution has been taken to prevent fire risks, the sides, roof, and bottom of the coach being entirely covered with sheet aluminium, and the bottom of the coach being furthermore covered with heavy asbestos sheeting, in addition to which, between the floor-boards, a large space which is left has been filled in with slag wool. Each coach is mounted on two pressed steel bogies with 42 in. wheels and 8 ft. wheel-base. The overall length of the coach is 60 ft. and 41 ft. between bogie centres, the width over centres being 9 ft. Besides ordinary hand-brakes, Westinghouse air-brakes of the most modern type are installed throughout the train.

In order to avoid danger of interference with the many telephone and telegraph circuits which exist along the line, the overhead wires in the majority of cases have been removed and the circuits carried in lead-covered air-space cables, metallic returns being substituted for earth returns. A difficulty in connection with the low bridges at Victoria Station was that, as the railway servants have to work upon the roofs of trains, the overhead conductor had to be placed at a height of 21 ft., rendering it necessary to design a special form of current collector bow capable of working satisfactorily at high speeds through a range of between 21 ft. and 14 ft., giving a vertical movement of 7 ft.

The electrical and mechanical equipment has been carried out to the designs and under the direct supervision of Mr. Philip Dawson, M.Inst.C.E., the Electrical Adviser of the Brighton Railway Company, and the repair-shops and switch-cabins have been designed by and built under the supervision of Mr. Charles Morgan, M.Inst.C.E., the Company's Chief Engineer.

The contractors for the whole work, with the exception of the coaches themselves, are the Allgemeine-Elektricitäts-Gesellschaft of Berlin. The coaches and trucks were manufactured by the Metropolitan Amalgamated Carriage & Wagon Company of Saltley. The whole of the overhead line equipment and general electrical equipment of the line, including cables and switchgear, was carried out by Messrs. R. W. Blackwell & Co., who are sub-contractors for this section of the work. Messrs. Siemens Bros. & Co. and Messrs. Johnson & Philips supplied the cables, and the switchgear in the switch-cabins was manufactured by the British Thomson-Houston Company of Rugby.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

AT an ordinary meeting of the Faraday Society, held on Tuesday, Dr. Samuel Rideal read a Paper on the "Application of Electrolytic Chlorine to Sewage Purification and Deodorisation by the 'Oxychlorides' Process." The original electrolyser employed by the Oxychlorides Company was a semi-circular wooden trough, lined with graphite on a metal base, which formed the anode. The cathode was a wooden cylinder covered with lead, and was provided with a slip-ring and brush gear. During the operation of electrolysis the cathode was rotated to ensure even concentration of the electrolyte. The more recent form of electrolyser is almost completely circular, except for a 4 in. hole, which is open to admit of the escape of the gases produced during electrolysis. The first-mentioned electrolyser had an active electrode surface of 30 sq. ft., and the second has a surface of 57·5 sq. ft. The graphite electrode blocks are of the purest form of Acheson graphite, and are specially treated at the Oxychloride Works by a secret process, which considerably adds to their life.

For most purposes this form of electrolyser is quite satisfactory, but when the solution requires to be removed considerable distances, as, for example, in paper mills or for bleaching cotton, linen, &c., the loss in active chlorine is considerable and the consumption of salt high. In order, therefore, to get over these difficulties, the most recent cells have a diaphragm which separates the anode from the cathode compartment. With this last pattern of cell, employing a current of 1,500 amperes at 4·6 to 5 volts—according to the concentration of the salt solution—an efficiency of 68 per cent. (calculated on active chlorine) is obtained. When the diaphragm arrangement was first employed considerable difficulty was met with, owing to the large amount of chlorate formed, namely, an amount equivalent to from 9·5 to 12·5 per cent. of the available chlorine. This has now been reduced to about 3 per cent. The advantages claimed for the diaphragm system are:—Elimination of the circulation of the electrolyte; reduced quantity of the electrolyte handled daily, with consequent reduction of cost for labour and power; smaller salt consumption; increased production per h.p. hour; and reduced cost per kilogram of available chlorine.

The rest of the Paper was devoted to a description of experiments in connection with the application of chlorine to sewage. One important point brought out is the rapid manner in which the chlorine in the form of hypochlorites will deodorise the sewage effluent. Even large quantities of the hypochlorite did not appear to permanently interfere with the working of the bacterial beds. Moderately dilute solutions, sufficient to deodorise the effluent, were found to actually help the bacterial beds. In ordinary practice there is a great tendency for choking of the pipes, which discharge on to the beds with a slimy deposit. This deposit was very much less when the effluent was first treated with the hypochlorites, and there was a reduction in the amount of grey gelatinous growths on the beds. The conclusion is, therefore, that electrolytic hypochlorite treatment is most useful for deodorising sewage effluent, and is a valuable adjunct to the after-bacterial treatment of the sewage. The bulk of the experiments were carried out in connection with the sewage works of Guildford.

P. Askenasy, W. Jakowsky, and A. Waniczek have carried out experiments in connection with the manufacture of aluminium carbide (*Chemiker-Zeitung*, February 4th, p. 63). In order to prepare the carbide, a mixture of alumina and charcoal was mixed with starch paste and moulded into briquettes. After drying these briquettes were heated in the electric arc in order to cause reaction between the carbon and the aluminium oxide. By this means a yellow carbide was produced which could readily be picked out from the unchanged black mixture. If this product is heated by itself much above the temperature at which aluminium melts, it is decomposed into its components again. The reaction is therefore a balanced one:—

$$Al_4C_3 \rightleftarrows 4Al + 3C.$$

At temperatures below the melting point of aluminium it goes from right to left, at higher temperatures from left to right. The yield of carbide may be considerably increased by heating to a high temperature and then suddenly cooling.

Although zinc protects iron from rusting when the iron is perfectly coated, yet the difference in potential set up between the iron and the zinc, should scratches arise, causes rusting to be very rapid at such places. Drs. Langbein and Pfanhauser (German Patent 203,100) suggest getting over the difficulty by first coating the iron electrolytically with lead. Zinc is then deposited upon this lead coating and forms an alloy with the lead. By careful heating the lead and zinc can be caused to form a complete alloy, which, owing to its softness, is less liable to scratch than the more brittle zinc.

Electrical Company Registrations.—According to the *Investors' Guardian and Joint Stock Companies' Review*, the nominal capital of electrical companies registered in England in 1908 was £1,791,025 as against £2,200,635 in 1907, and £4,993,312 in 1906. The figure for 1908 is the smallest for the last ten years.

A.-C. MEASUREMENTS BY POTENTIOMETER METHODS

DR. C. V. DRYSDALE, in a Paper read before the Physical Society on January 22nd, said that the great difficulty in alternate-current measurement lies in the shortness of the range of the instruments available. He suggested two methods of attempting to apply the potentiometer principle to alternate-current measurements: (*a*) the balancing of the alternate-current P.D. against a continuous P.D. with the assistance of some suitable balancing device, or (*b*) the balancing of two alternate-current P.D.s against one another. Potentiometers on the first principle seemed unlikely to be successful owing to the insensitiveness of square law instruments at low voltages; and the second method presented difficulties in that the two P.D.s to be compared must be identical in magnitude, phase, and frequency, and approximately so in wave-form. The author's recent experiments with a phase-shifting transformer had led him, however, to attempt to use it with a potentiometer, and the measurements are then made in the same manner as with an ordinary direct-current potentiometer, except that a vibration galvanometer or telephone is substituted for an ordinary galvanometer. By interposing an ammeter on the dynamometer principle in the main circuit of a potentiometer and deriving the current from the secondary of a phase-shifting transformer, it was possible to check the instrument with direct current against the standard cell in the ordinary way, and then to reproduce the same current in the potentiometer circuit and to bring it into coincidence of phase with the P.D. to be measured.

The tests so far made seemed to indicate that an alternate-current P.D. of 0·1 volt could be measured to an accuracy of 0·2 per cent. or closer. The author had also designed a universal potentiometer on this principle, which served both for direct and alternate-current measurements.

In the discussion, Mr. A. Campbell remarked that the first method suggested by the author had already been described by Mr. J. Swinburne (Phys. Soc., December, 1893). It was also used with success at the Reichsanstalt in an improved form by Dr. Drewall (*Zeitschr. für Instrumentenkunde*, April, 1903). Dr. Drysdale's phase-turning method was interesting, but the vibration galvanometer was so very much more sensitive for its own frequency than for others that it would not be likely to give any indication of errors due to other harmonics unless they were very pronounced. Hence the method must be used with great caution. In reply, Dr. Drysdale said that for ordinary standardisation of P.D. and current, this difficulty did not present itself, as there was no difficulty whatever in obtaining a sufficiently closely sinusoidal wave-form, and the wave-forms of the measured and balancing P.D.s were usually similar, being derived from the same source. For inductance and capacity measurements there was, of course, a positive advantage in an instrument which disregarded the harmonics. In reply to a suggestion by Mr. Duddell, he said that there was no doubt that the vibration galvanometer did give back E.M.F., and this would probably increase the damping, but he did not know the amount of the influence on the sensitiveness. In answer to Mr. Paterson, he said that he was certain that no ordinary low resistance standards would give any appreciable inductive errors.

Heriot-Watt College, Edinburgh.—The committee of the George Heriot Trust has instructed the Principal of the Heriot-Watt College to prepare a letter to the Scotch Education Department requesting a further contribution from the General Aid Grant towards the expenditure necessary for the improvement of the Electrical Engineering Department.

Electricity from Peat.—The announcement was made some months ago that the Siemens-Schuckertwerke had obtained a concession from the Prussian Government for power supply in the East Friesland peat district. A large power station consuming peat only is to be built near Aurich, and the towns of Emden, Wilhelmshaven, and Leer are to be supplied from there, as well as numerous other smaller towns. According to *Elektrotechnik und Maschinenbau*, the development of this scheme has already commenced. A navigable canal in connection with other canals is being cut through the moor, and a small power station for supplying energy for the electrically-operated excavators has been erected. This station contains one 200 h.p. steam engine and two boilers. One of the latter is fired with air-dried compressed peat, and the other with undried peat. The machines for compressing the peat are electrically driven. If experiments with undried peat prove successful, some of the boilers in the large projected power station will be fired in this way, but most of them will be run with dried peat. The latter station will contain three 1,800 h.p. steam turbines. It is expected that the erection of this station will be commenced shortly, and that it will be completed in the autumn. Contracts have already been made with the above-mentioned towns for a supply of electrical energy. A large peat-consuming station is being built by Gebr. Körting Akt.-Ges. in Holstein, but in this case gas engines supplied from producers burning air-dried peat will be used in place of boilers and steam engines.

THE ELECTRICAL INDUSTRY AND TARIFF REFORM

VOLUME IV. of the reports of the Tariff Commission deals with the engineering industries, and embraces structural, electrical, marine, and shipbuilding, mechanical and general industrial engineering. The report includes an introduction, an analysis and summary of the evidence and statistics, followed by the verbatim evidence. There are, in addition, 61 tables giving details of various imports and exports in relation to the United Kingdom.

It is pointed out that whereas the expansion of British engineering generally is traceable in part to traditional inventiveness, skill, and enterprise; in part to the extension of traction and other services by municipalities and private companies, and the increased uses of electricity for lighting, heating, power, and traction within the United Kingdom in directions largely beyond the reach of foreign competitors; some branches of engineering, such as the electrical and motor industries, were in their early days impeded by legislation which held back the British industries, and at the same time foreign industries were built up with the aid of tariffs, and established themselves in the British market. Witnesses also maintained that the obstacles in the way of schemes for inter-urban traction and power have hindered the development of the British electrical industry. A deterrent influence has been the extent to which British municipalities have placed contracts with foreign manufacturers who are often willing to accept prices below the competitive level in order to establish themselves in the British market. These foreign firms, then, hold a preferential position for orders for subsequent renewals and extensions frequently at enhanced prices. This action of British municipalities has greatly aided in building up the German electrical industry, which now competes keenly in British home and export markets.

This competition is, to a very large extent, unappreciated owing to the extremely curious classification adopted in the Board of Trade returns, for out of £5,250,000 of engineering imports in 1907, not less than £3,000,000 worth remains unclassified, whilst no details are given of £11,000,000 worth of exports. In this way items of one-half of the electrical importations are unenumerated. Although material changes have been made in this direction for the year 1908, the main effect is to improve the classification of those goods which were previously classified. Foreign competition in electrical material is said to be keener in neutral and colonial markets than in the British market, but the preference has been most beneficial in respect of some British electrical goods. It should be pointed out that in the main the report offers few independent opinions, but records those of the witnesses whose evidence it publishes. The following gave evidence upon the electrical engineering industry: A. Bergtheil (Messrs. Bergtheil & Young, Ltd.), Hugo Hirst (General Electric Co., Ltd.), W. L. Madgen (Brush Electrical Engineering Co., Ltd.), Mr. T. O. Callender (Messrs. Callender's Cable & Construction Co., Ltd.), and witness "No. 248," whose name is not given.

The following is an abstract of the main points of the evidence in relation to the electrical engineering industry, without specifically mentioning names, with the addition of information of a general character bearing on the subject.

In regard to manufacture and commercial energy the lead in many directions was British. But despite this lead the British electrical industry remained practically stagnant for many years largely in consequence of obstructive legislation respecting electric lighting and traction and power undertakings, while foreign manufacturers, being free from legislative restrictions, profited by British initiative and capital, and, aided by their tariff systems, built up a solid and progressive business in their own countries as well as in the United Kingdom. Some doubts are expressed whether, in view of the strong position of the foreign industries, British manufacturers can now ever effectively compete with their foreign rivals, but the more general impression is that, given more equitable conditions, considerable progress may be anticipated. This foreign competition has in the opinion of witnesses been considerably assisted by the action of British municipalities in placing contracts abroad. Some of these municipal contracts are, it is alleged, given to firms with English names in the belief that they are English firms, when they are really German firms or the agents for German manufacturers. When, on the other hand, British firms have sought business in Germany they "have been refused even the forms of tender unless they could guarantee that the goods would be manufactured in Germany." Instances are given in the evidence of contracts for electrical productions placed abroad by public bodies in London, Manchester, Glasgow, Hull, and other places, although "the difference in price between English and foreign tenders has been quite insignificant." One of the cases cited in detail is that of the Manchester Corporation, where, to make a nominal saving of "a few thousand pounds," a contract valued at £100,000 was given abroad with a loss of £15,000 to £20,000 in wages alone in the British electrical industry, not to speak of the losses in the auxiliary industries of this country. Belgian competition was most felt when the Belgian works had to find an outlet at any price. On a tender for St. Pancras of £12,000, in which the witness's firm was the lowest of six English manufacturers, a German company quoted £11,000, but a Belgian firm quoted £7,000, and got the contract. "They made no profit on it, and have since reduced their capital by about 5 to 1, but, none the less, we suffered at the time." According to the 1908 lists, the contracts for dynamos and alternators alone represented a total capacity of nearly 108,000 kw. Of this total more than 87,000 kw. (or 81 per cent.) is in plant of foreign origin.

Emphasis is laid in the evidence upon the assistance which this placing of British contracts abroad gives to the foreign manufacturer to cut out the British manufacturer in the British home market. In some cases, where the foreigner has done this municipal work at a somewhat lower price than the British tenderers would have done, experience shows that on "repeats" and extensions the prices have been higher than British prices, and municipalities have had to accept these higher prices because of the difficulty involved in adapting British machinery to existing foreign plant. Another feature is the financial side of the question. By giving their contracts abroad, British municipalities strengthen the hands of foreign financial institutions in their policy of reserving their own work for their own home industries. German electrical undertakings are financed by, and remain in the most intimate association with the German banks, and whenever German financiers finance undertakings abroad, it is stipulated that the plant and machinery for these undertakings shall be produced in Germany. In the United Kingdom there is no such association between the financier and the industrial, and no such stipulation occurs.

It is strongly urged that any monopoly or special privilege enjoyed by the electric light and power stations under municipal control should be accompanied by a corresponding obligation for the benefit of British industry and labour. As in Germany, it is suggested that municipalities and such corporations as tramway, railway, gas, and water companies enjoying public charters should be compelled within reasonable limits to favour the home manufacturer and workman. As it is, British manufacturers are said to have been compelled to accept prices set by foreign competitors, although in many cases those prices are estimated to be from 10 to 25 per cent. below British cost and, indeed, amount to no more than the cost of the raw material and labour employed.

In regard to the legislative difficulties that still remain, it is suggested that our "narrow parochial policy has put back the construction of probably some thousands of miles of light railways, and of large main power-stations for supplying electrical energy on a wholesale scale. By granting local municipal monopolies, the legislature has 'picked the eyes out of the mine,' to borrow an expression common among mining engineers—that is to say, there has been no statesmanlike provision for the orderly and systematic development of the country's opportunities of benefiting by the practical application of electrical science. Consequently, throughout a country which in numerous districts has clusters of towns ideally situated for light railway connection, there are many inconvenient gaps in the track, and there are many sites exceedingly well adapted for industrial settlement lacking the attraction of cheap electric power."

The progress and development of the cable trade are attributed to the fact that the business was founded for the purpose of submarine telegraphy. Foreign competition has much increased. A few years ago "practically none of the home trade in the manufactured articles was done by foreigners." Whereas in the year in which the evidence was given "they did at least £200,000 worth of our trade chiefly in smaller wires." The competition is chiefly German. The British export trade has also been much interfered with by foreign tariffs. The German trade of one firm giving evidence "absolutely disappeared" when the present German duties were put on. The same applies to France, where there were extensive British contracts; that market is now closed to the contracting firm. Other Continental markets are now similarly protected. In Canada the United States is firmly established largely by reason of the financing of Canadian companies by United States capitalists.

The incandescent lamp industry is comparatively new, and the demand has grown enormously, but the volume of British business has not increased in the same ratio as the demand. The consumption in the United Kingdom is now probably about 20,000,000 lamps per annum, of which about 7,000,000 are imported. The Colonies probably use 4,000,000 to 5,000,000, out of which Great Britain supplies, say, 1,000,000. The consumption is increasing enormously, because once a lamp is installed it has to be replaced periodically. Notwithstanding this enormously increased demand, it is said that few of the undertakings that started making incandescent lamps in England in 1893 have survived, and these only because they endeavoured to produce a superior article, and appealed, not quite without success, to the patriotism of English consumers. The advent of the metallic filament lamp is a feature of the highest importance to the industry, and under equitable fiscal conditions and by aid of the new Patents Act it is hoped to

Digitized by Google

retain this trade for the British industry. Instances are given in which lamps have been sold in this country at under-cost prices in order to kill British competition, and municipalities and other corporations who are very strict when placing contracts as regards the rate of wages paid to workers and the regulation and management of factory buildings have snatched at these offers without considering the harm thereby done to the British workman. Foreign-made lamps are said to be sold under English names or by foreign concerns whose style suggests home manufacture.

The advent of electric light and power has created a very large demand for carbons, and the United Kingdom possesses the best raw material. The conditions therefore appear to exist for the foundation of an industry of the greatest importance. The failure to establish such an industry is attributed by witnesses to the absence until 1907 of a compulsory manufacturing clause in the British Patent Law as well as to the general backwardness of the electrical industry in the United Kingdom. The price at which foreigners were selling in this country is said to have been the absolute cost price of material, plus labour, without any general expenses or profit added. The manufacture of carbon filaments for the ordinary incandescent lamps is an English industry by itself. Germany can supply itself; Austria and the United States can supply themselves in part. There is no want of raw material in the United Kingdom, and manufacturers say that carbons can be produced more cheaply here than they can in foreign countries, but that with the unfair advantage given to the foreign manufacturer in the British market it is almost impossible to make the industry pay. The British manufacturer has no encouragement to find labour and train it—a tedious and expensive process. The special encouragement of this manufacture is further advocated on military grounds. It is held to be of vital importance that we should be able to supply our own wants for the Army and Navy. The industry is said to have benefited from the Canadian preference.

The manufacture of electric supplies which was flourishing up to about 1895 has since considerably declined. A number of English firms produced fittings of admitted superiority, and the English Potteries supplied a considerable amount of raw material for such fittings which were better than the foreign production. More than one-half of the trade in this country is said to be supplied from abroad, but the official returns give no definite information on this point, the identity of this item being lost in the "unenumerated" group. The estimate of one witness is that the annual British consumption is of the value of from £300,000 to £400,000, of which about one-half is supplied from abroad, and the proportion of foreign to British is increasing. In electric lamp-holders, switches, fuses, and-cut-outs, the English manufacturer cannot, it is said, compete with the German.

The official returns contain no record of the imports of electrical machinery before 1903 and of other electrical goods before 1900. In 1907 the total imports of electrical machinery amounted to £603,000, of which Germany, Holland, and Belgium provided £359,000, and the United States £186,000. Since 1903 there has been a decline of £120,000 in imports from the United States, synchronising with the establishment of works in this country by United States firms. The imports from other countries have increased £168,000 since 1903, chiefly from Germany. The separate classification of electrical goods other than machinery began in 1900. Since that year the returns show considerable fluctuations due entirely to the United States trade. The imports from other countries have increased in the same period from a total of £433,000 to £1,186,000, or £753,000, of which Germany, Holland, and Belgium account for £563,000. Nearly one-half of the import trade is still unclassified, thus defying analysis as in so many other branches of the engineering industry. It is obvious, however, from the evidence that these unenumerated items must include lamps, fittings, and carbons. The chief enumerated items for 1907 are telegraph and telephone cables (chiefly from Germany), £234,000; other electric wires and cables (also chiefly from Germany), £160,000; telephone and telegraph apparatus (chiefly from Belgium, Sweden, and Germany), £258,000.

For the last five years the export of electrical goods of all kinds other than machinery has remained stationary at about £2,500,000. Prior to 1902 the average exports increased from just under a million in the period 1836-89 to £3,501,000 in 19[illegible]. Nearly the whole of this increase took place in the last period, and is due almost entirely to the development of cable enterprise affecting the exports to Madeira, Azores, the United States, and Canada. The total for this group, telegraph wire and apparatus, averaged £2,929,000 in the years 1900-02, which is far in excess of any previous period. The increase as compared with the period 1895-99 is £1,923,000, of which £467,000 consists of increased exports to Portugal and possessions; £299,000 to the United States; £286,000 to Australasia, and £314,000 to Canada. Returns of the exports of electrical machinery do not exist for the years prior to 1903. Since then there has been a steady and large expansion from £437,000 in 1903 to £996,000 in 1907. The principal markets have been India (from £106,000 to £171,000), Australasia (from £73,000 to £139,000), Japan (from £39,000 to £129,000).

The position as to electrical exports generally is summarised as follows in the evidence: "Our best export markets, at present, are India, Australasia, and South America. South Africa has become more and more the cockpit of international competition. The severity of American and German competition is largely due to the fact that their industries start with the enormous benefit of protected home markets. Their tariffs are practically prohibitive, and, being secure in their own home fields, they are, of course, able to produce for export at a cost with which it is increasingly difficult to compete." Notwithstanding these drawbacks, however, the volume of business done in electrical engineering has materially increased, some conditions have been improved, our external trade is a steadily growing one, and, properly fostered, would, it is believed, be equal to our home trade in a few years. But the trade has not increased in proportion to the increased demand, foreign importations now representing a larger share of the total consumption. It is maintained, however, that the firms who have held their own have been those who have found the capital and also the market in which to dispose of their commodities in quantities sufficiently large to be remunerative. Smaller works and smaller factories cannot compete and are disappearing. "When British enterprise and British capital have been employed in establishing industries in protected countries, the results have, in general, been successful; whereas the experiments of foreign manufacturers in erecting subsidiary factories in Great Britain have, on the contrary, demonstrated that the qualities which some critics attribute to them do not enable them to carry on business to better advantage than the native born, however brilliant may have been their achievement under the easier conditions abroad." In certain electrical apparatus, the quality of English work is exceedingly high, and the superiority in some respects of English machines will at times lead engineers to give home manufacturers a slight preference. Thus, apart from any question of design, English dynamo electrical machinery is reputed to be more workmanlike and better finished than imported machinery, the production per man also is said to be higher than on the Continent, and about equal to that obtained in the best United States shops, and these results are obtained although the British shop hours are appreciably shorter.

It may be pointed out that the evidence given by Mr. W. L. Madgen, of the Brush Co., was not given on behalf of the Board of the Company, one or two of his colleagues not being quite in accord with him. In addition to the witnesses mentioned above, replies bearing on the subject were received from 33 electrical engineering firms, who, for the most part, were not agreeable to having their names published.

EFFECTIVE RESISTANCE AND INDUCTANCE OF CONCENTRIC AND TELEPHONE CABLES

AT a meeting of the Physical Society on January 22nd, Dr. Alexander Russell gave the solution of the problem of the effective resistance and inductance of a concentric main in terms of Kelvin's ber and bei functions, and of two analogous functions which he calls ker and kei functions. The formulæ given previously by Maxwell, Rayleigh, Heaviside, Kelvin, and Sir Joseph Thomson were shown to be particular cases of his solution. The following formula for the effective resistance R, per centimetre length, of the inner conductor of a concentric main for high-frequency currents was obtained:—

$$R = (\rho m / 2\pi a)\ (0{\cdot}7071 + 1{\cdot}2ma + 0{\cdot}265\ m^2a^2 - 0{\cdot}35/m^4a^4),$$

where ρ is the volume resistivity of the conductor, a its radius, $m^2 = 8\pi^2\mu f\ \rho$, μ the permeability of the conductor, and f the frequency of the alternating current. This formula, the author said, may be used in wireless telegraphy for calculating the resistance of a conductor when other conductors carrying high-frequency currents are not too close. For values of ma greater than 6 the maximum inaccuracy of the formula is less than 1 in 10,000. The case of a concentric main with a hollow inner conductor was also considered, and approximate formulæ suitable for power transmission cables were given and numerical examples worked out.

Mr. W. Duddell said that the results obtained in the Paper would be most useful. It was, he said, customary in dealing with high-frequency currents to use several parallel insulated wires instead of a single wire in order to increase the surface and obtain greater conductivity. He asked the author to what extent it was advisable to do this. He also asked how far it was valuable to silver-plate copper wires for high-frequency currents.

Mr. A. Campbell observed that Dr. Russell's warning that inductance standards might be greatly dependent on frequency, was not necessary in the case of well-designed single-layer wavemeter coils of highly stranded wire.

Dr. W. H. Eccles remarked that in high-frequency work the resistance of a conductor depended on the nature of the surface. If a copper wire tarnished its resistance altered. Uniform results could be obtained by lacquering the wires.

Mr. B. S. Cohen said that a knowledge of the variations with frequency of effective resistance and inductance of copper conductors was of considerable importance in connection with telephonic transmission, and it was to be hoped that Dr. Russell would extend his valuable investigations to conductors lying

Digitized by Google

side by side. The heaviest gauge of conductors met with in general telephonic practice is 2·85 mm. in diameter in the case of cables, and these conductors are separated by about 2·5 mm. of combined paper and air dielectric and twisted together with a lay of about 15 cms. In the case of overhead open wires, the largest conductor in general use is 4 mm. in diameter, although in a number of cases a 5·69 mm. conductor has been used. The mean axial distance apart of these conductors is about 35 cms. as they are rotated in sets of 4 in a foot square. Applying Lord Rayleigh's formula for effective resistance in these cases we get, for a frequency of 1,500 periods per sec., an increase of 1 per cent. in effective resistance over steady current resistance in the case of the 2·85 mm. cable wire. A frequency of 1,500 can quite safely be taken as the maximum frequency which is of any importance in speech articulation. The increase with the 5·69 mm. open wire at this same frequency is 12 per cent., and with the 4 mm. wire it is 3·55 per cent. In a table given in a well-known pocket book, a 5·69 mm. conductor is stated to increase 15 per cent. in effective resistance at 1,500 periods per sec., and he noticed that this figure had been adopted by one writer on telephonic matters. Mr. G. M. B. Shepherd some time ago worked out the decrease in inductance with frequency for wires lying side by side by both Heaviside's and Rayleigh's formulæ. The following percentage variations between 0 and 1,500 periods per sec. were found for 5·69 mm. wire:—L 0·37 per cent. decrease; r 0·22 per cent. increase. This is very small, and is due to the fact that most of the inductance is due to the field between wire and wire. On the other hand, increase of resistance in this wire at 1,500 periods per sec. means an increase in attenuation of 12 per cent. In the case of 5·69 mm. conductors 33 cms. apart, the inductance as calculated by Maxwell's formula amounts to 3·2 millihenries, which would reduce the attenuation constant to one-fifth of its value at 1,500 periods. Lastly, he asked Dr. Russell whether he thought that the presence of the adjacent conductors in a telephone cable or open wire route was likely to modify the skin effect to any decided extent.

Dr. Drysdale suggested a graphical method for facilitating the use of these and other calculations.

The Author, in reply to Mr. Duddell, stated that in his opinion stranding and insulating the strands of the wires used in wireless telegraphy would not diminish the skin effect if the strands were parallel to the axis of the wire. It would probably increase it. Silver-plating the wires would be beneficial. The distribution of the high-frequency current on the surface of the wires can sometimes be found by remembering that the distribution is such that no magnetic induction is produced in the metal. The corresponding electrostatic problems are consequently of great help. The coils mentioned by Mr. Campbell would be of little use for many experimental purposes. With ordinary laboratory coils a frequency of 10,000 will alter the inductance 2 or 3 per cent. If we have two parallel cylindrical wires practically touching, the inductance will alter from 5·7726 cms. per unit length to practically zero as the frequency is increased.

CORRESPONDENCE

ELECTRIC POWER AND SUCTION PLANT.

To the Editor of Electrical Engineering.

Sir,—Referring to your issue of the 28th ult., and to the article on the letter sent out by the electrical engineer of Warrington, and the replies received thereto from different towns, one cannot help being struck by the vagueness of some of the statements; and in very few cases are any reasons given why the change from suction-gas to electricity was made. On the other hand, we have numerous instances on our books where people originally used gas engines, then tried electricity, and have since reverted to gas engines, but we admit that a few isolated instances on either side do not conclusively prove the failure either of suction-gas engines or of motors. We may add, however, that we have before us the annual cost of working a gas engine driven electrical plant, which, taking all capital expenditure, interest and depreciation, stand-by losses, labour, water, oil, repairs, renewal, &c., shows that the total cost of one kilowatt hour at the switchboard is ·35 of a penny, and this when working with fuel at 15s. 6d. a ton. We think that this is a figure at which very few electric supply companies could afford to supply current to manufacturers.

Yours faithfully,
Crossley Brothers, Ltd.,
D. H. Irwin,
Managing Director.

Manchester.
February 3rd, 1909.

ELECTRIC POWER SUPPLY IN THE UNITED KINGDOM.

To the Editor of Electrical Engineering.

Sir,—Referring to the abstract of my third Cantor Lecture which appeared in your issue of the 4th inst., will you kindly allow me to correct one or two points in which you have not interpreted my meaning correctly?

In explaining the methods of isolating faulty sections on distributing networks, I pointed out that there were two leading systems, the time element system and the system of using balanced transformers, of which the most perfect example is the Merz-Price system. I did not then say that the latter system was "By no means perfect, especially in complicated systems." This observation was intended to apply to the time element system, which I stated was suitable for the simpler classes of circuit but was not adapted to complicated systems. On the other hand, I spoke highly of the Merz-Price system, saying that although this was expensive owing to the necessity of using pilot cables, and required the use of intelligence, yet it was a great merit in it that it could be used for protecting systems however complicated, and in this respect I thought it marked a real advance in high pressure distribution.

Again, when discussing the gas engine, I did not say that where gas is produced from coal it could not compete with steam plant, but pointed out that the weak point in the gas engine system was at present the producer, and my argument was to the effect that the amount of skill and experiment which would be needed to improve the producer to such an extent to adopt it for central station work if employed in improving the boiler plant would no doubt lead to considerable economies in that direction, and thus the change over from steam to gas might be delayed a long time, though I was careful to point out that the additional advantages gas engines would have where coal was dear would be a strong incentive to their adoption in such places.

Further, when speaking of the saving of coal to be effected, I pointed out that in the industrial districts the saving of coal would not enable more than a 10 per cent. reduction to be made to a customer taking a supply for ordinary hours, not that the working cost would be reduced 10 per cent., as you have it.

Lastly, in dealing with the legal side of the question, I am sorry you omitted my main argument, in which I showed how hardly the purchase clause bore on the smaller classes of undertaking, and the great necessity for its amendment, while giving at some length the recommendation I made as to allowing applications for Provisional Orders to be made twice in the year, which, while in itself desirable, is, of course, quite a subsidiary point as compared with the question of the purchase clause itself, which I pointed out was likely to block the application of capital altogether to this class of work.

Yours faithfully,
G. L. Addenbrooke.

53 Victoria Street, S.W.
February 5th, 1908.

RE ECLIPSE BOILER FURNACE COMPANY.

To the Editor of Electrical Engineering.

Dear Sir,—With regard to the claims put forward for the above apparatus, it is difficult to devise a letter in reply that is not palpably an advertisement, but we beg you will allow us to say that we can confirm the statements respecting mechanical stoking made by one of your correspondents in your issue of January 28th, and may state that we have several installations of stokers at work in London, which have for years been burning low-grade bituminous slack smokelessly and showing a saving, as compared with Welsh coal, even greater than is claimed for the "new" furnace.

Yours faithfully,
Ward & Cuningham.
Agents for Triumph Stoker, Ltd.

Craven House, Kingsway,
London, W.C.
February 2nd, 1909.

WIRELESS TELEGRAPHY AT SEA.

To the Editor of Electrical Engineering.

Sir,—I have read with much interest, in your issue of January 28th, the account of the saving of the *Republic* by wireless telegraphy. You state that already a member of the House of Representatives has introduced a Bill to make it compulsory for all ocean-going passenger steamers to have wireless telegraph installations, and you suggest that in such cases they should carry a relief operator. It is to be hoped that the representatives of a nation, which owns the largest share of the world's passenger steamers, will not remain silent and indifferent to the enormous value to mankind of this form of communication, which is unaffected by either storm or fog, and that similar legislation will be introduced by Parliament during the coming session.

Yours, &c., C. E. M.

Digitized by Google

RECENT DEVELOPMENTS IN MACHINE STOKERS

A LECTURE on this subject was given last week before the Bradford Engineering Society by Mr. A. W. Bennis. In the introductory portion of the lecture he referred to the fact that much more difficulty was experienced in furnace design in ensuring the proper burning of the gas produced during the combustion of the coal than of the coal itself. The object of the furnace designer was to keep the products of coal distillation as hot as possible, but the object of the boiler designer was to take all the heat out of them in the least practicable time, so that a compromise had to be effected.

For the purposes of description the lecturer divided mechanical stokers into four classes, namely, sprinklers, intermittent sprinklers, cokers and chain-grates, and underfeeds. A modern example of the first class was the Leach stoker, which consisted of a pair of fans and fan-boxes to each flue, each with an oscillating deflecting plate placed over the orifice through which the fuel was thrown on to the grate. The Hodgkinson and Whittaker patterns also had deflecting plates, fan throwers, and stationary, rocking, or moving furnace grates. The Proctor stoker, which was an example of the second class, was similar to the early Bennis stoker, in that both had spring-actuated mechanism for intermittently throwing the fuel on to the fire, but the feed motion was different. The feed mechanism of the Proctor stoker now consisted of one hopper to each flue and a feed-box underneath, which contained an adjustable reciprocating feed ram. The shovel for throwing the fuel worked immediately underneath.

In the modern pattern of the Bennis intermittent stoker, the author continued, there were two hoppers to each boiler. Under each hopper was a feeding-box, in which was a pusher plate with an adjustable reciprocating motion. The fuel fell in front of the pusher plate, and was pushed over a ledge formed by the bottom of the feeding-box. The fuel then fell on to a flat plate called the shovel-box, from which it was projected into the fire at intervals by a V-shaped shovel. The shovel was actuated by a coiled spring enclosed in a cylinder and pressing on a piston. Any remaining force at the end of the stroke was taken up by an air-cushion. The cam that drew back the shovel had four varying lifts; the effect of this was the scattering of the fuel on the fire in four divisions, each about 18 in. long, so that in a 6-ft. furnace the fuel was thrown on only a quarter of the fire at once, and each portion of the fire had time to become incandescent between the charges.

After mentioning some improvements in the details of the mechanism of the Bennis stoker, the author passed on to a consideration of cokers and chain-grates. The Vicars coking stoker, he said, comprised a hopper, usually one to each furnace, from which the coal was fed into two boxes. From these it was pushed by reciprocating plungers working in the ram boxes, on to a perforated dead-plate, where it ignited. From the dead-plate it was pushed on to the moving bars, whence it gradually travelled down to the back of the furnace. In the Hodgkinson stoker a reciprocating ram placed just over the fire-door pushed the fuel out of the feed aperture over a deflecting plate and on to a dead-plate. Here the fuel became coked, and thence passed down the fire-bars. The volatile hydrocarbons liberated at the dead-plate had to pass over the incandescent fire, where, if sufficient free air was admitted, they burned smokelessly. The makers recommended induced draught where much fuel per square foot of grate was to be burnt, but, in the author's opinion, a good draught was beneficial to all coking and sprinkler stokers where high duty was required.

Coking stokers as a class, continued the author, were admittedly an absolute preventive of smoke, when not worked beyond their limits, and in addition prevented the emission of grit or dust from the chimney top, when not used with too strong a fan draught. The disadvantages of coking stokers were the inability of the fire to light back at more than a certain speed due to the lowering of the temperature below combustion point if too much fuel was fed to the fire, and the cohesion of the mass of coked incandescent fuel passing slowly down the furnace grate, preventing the air blowing through the coke with any great velocity. In order to increase the rate of combustion, induced and fan draught had been advocated, but the lighting back effect could not keep pace with the extra burning capacity of the draught supplied, so that excess of air entered through the back end of the bars and lowered the efficiency. These defects were claimed to be overcome in the Bennis high temperature coking stoker, in which a live plate, composed of little bars, was substituted for the usual dead-plate. Below these bars was situated the main furnace, which was of the Bennis patent self-cleaning type. The effect of this was that there was always a white hot fire near the front at the two sides, and the blast of air through the air spaces of the bars and of the live dead-plate bars, was such that the whole of the fuel being fed across the fire was lighted up quickly within a few inches of the live dead-plate bars.

Chain-grate stokers, said the author, were only applicable to water-tube or under-fired boilers, and were not smokeless without an incandescent arch of considerable length. In the Babcock & Wilcox chain-grate stoker, recent improvements consisted in a new link with closer air space, which did not allow so much small coal to drop through into the ash-pit, and the dumping bars had also been lowered somewhat so as to protect them from the action of the fire. The drive, instead of being by ratchet and pawl, was now by chain to a Panhard change-speed gear-box, and was, therefore, continuous. In the Bennis chain-grate stoker great care had been taken to prevent the leakage of air through the fire doors, &c., into the furnace. The usual dumping bar was entirely eliminated in this stoker. Ashes and clinker tipped over on to an air seal, from whence they could be removed without stopping the running of the stoker.

The fourth and last class, underfeed stokers, was, continued the author, akin to the coking stoker class, inasmuch as the fuel was fed against a mass of hot coke, and the distilled hydrocarbons were burned over the hot coke bed. Instead, however, of feeding the fuel in at the front, they pushed the fuel underneath the already ignited fuel. In the underfeed stoker, a trough placed underneath the grate received the fuel from a hopper outside the boiler, and it was then screwed along the trough by means of a worm. Another type of underfeed manufactured by the same company was similar in construction, except that the coal feed in the conveyor trough was effected by means of small taper rams driven by a steam cylinder on the lines of a steam pump. This construction, so far as the feed and rams were concerned, was similar to the Erith underfeed stoker, in which the feeding was accomplished by means of a reciprocating steam ram. This ram pushed the fuel into a trough below the combustion point. An auxiliary rod forced the fuel along and upwards over the top of the trough.

Northampton Institute Conversazione.—The annual prize distribution and conversazione at the Northampton Institute took place on Friday and Saturday last, there being the usual crowded attendance, especially on the second evening, of the students and their friends. The Rt. Hon. the Earl of Halsbury, P.C., distributed the prizes on Friday evening, and subsequently opened the new courtyard extension. The report of Dr. R. Mullineux Walmsley, the Principal of the Northampton Institute, referred more particularly to the work of the session 1907-08, although some remarks were made touching upon subsequent work; and it once again demonstrated the activity with which the work of all branches of technical education is pursued at the Institute. This is well testified to by the continuing and growing need for additional accommodation. One unusual feature of the work of the session was that it extended throughout the year from September to September, there having been during July and August large and well-attended classes in telegraphy and telephony. The enrolments numbered 2,362, showing an increase of over 12 per cent. The number of student hours upon which the maintenance grant of the London County Council on the evening work is based increased to 137,461, being an average of 70 hours per student, averaged on the whole of the evening students enrolled, although the attendance of those students only are included who have made not less than 20 hours' attendance during the session. The following is a brief description of the new buildings:— For several years the work of the Northampton Polytechnic Institute has outgrown the accommodation provided in the buildings erected in 1896, and various schemes have been under discussion for increasing the accommodation. Eventually the necessary funds, amounting to £9,000, having been generously provided by the London County Council, it was decided to erect a five-storey building in one corner of the courtyard and to complete the roofing of the remainder of the yard so as to give a basement floor occupying the whole of the area. In the basement there is an extension of the mechanical engineering workshop, nearly doubling the capacity of that workshop, and adjoining it is a room which is to be utilised for experimental steam-raising and gas-producing plant. Further on, under the whole of the new building, is a large room, which will be equipped as a power laboratory. On the ground floor there are three large rooms, two of which are to be used for the meetings of scientific societies connected with the Institute and for the meetings of the Institute clubs respectively. On the first floor the additional accommodation provided by the new building is utilised almost entirely for a large lecture theatre. This is completely fitted with seats, lecture table, blackboards, and screen. On the second and third floors there are suites of rooms numbering 15 in all, which have been fitted up as class-rooms.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 4th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

433/08. **Manufacture of Aluminium.** H. HERRENSCHMIDT. In one process for the manufacture of aluminium, the bauxite or other aluminous earth is first reduced to alumina, which is then treated electrolytically. In another process, the bauxite is dissolved in a bath of molten fluorides, and the aluminium is afterwards electrolytically extracted. A third method consists in forming an alloy of the aluminium in the bauxite, by mixing it with molten iron or zinc, and subsequently extracting the aluminium from the alloy by an electrolytic process. According to the present invention, the raw bauxite is crushed, and then fused in an electric furnace with carbon and a compound of boron. The iron oxide in the bauxite combines with the boron, and the silica is decomposed, silicon being set free in the form of vapour. The molten alumina produced is allowed to flow direct into an adjacent chamber, where the aluminium is extracted. This combination of the processes of producing the alumina and extracting the aluminium is stated to lead to considerable economies in working; the bye-products also are valuable. Two claims.

2,175/08. **Combined Switch and Fuse.** J. A. KENNEDY-MCGREGOR and H. H. MOUNTFORD. This patent is for a switch, the contact member of which is retained in the closed position by a detent. The detent is held in position against the action of a spring by means of the fuse wire. Should the latter melt, the switch immediately opens, thus preventing arcing across the terminals of the fuse. Means for manually opening the switch without destroying the fuse wire are provided. Three claims, four figures.

5,829/08. **Control of Enclosed Flame Arc Lamp.** A. D. JONES (Jandus Arc Lamp and Electric Co., Ltd.). In flame arc lamps of the enclosed type with impregnated carbons arranged vertically, the arc is sometimes liable to burn unsteady, as the carbons become covered with a deposit and the arc tends to creep along this deposit up the side of the carbon. When two or more lamps are burning in series the effect is more pronounced. According to this invention, this trouble can be overcome by the use of a "blow" magnet of annular form placed above the arc. This may be of the shape of an inverted cone, the top carbon passing through the centre; it may be wound, but generally the magnetising effect of the current passing through the carbon in the centre is found to be sufficient. As the lower carbons in such lamps are thick and short, there is no need to arrange for the magnet to descend as the carbon burns down. The stray field from the magnet prevents the arc from rising up the carbon. Three claims, two figures.

6,971/08. **Improved Flicker Photometer.** W. FENNELL and W. P. PERRY. In the ordinary "flicker" photometer the eye sees alternately two surfaces illuminated respectively by the two sources of light to be compared, and the illuminations are equal when no flicker is observed. The general arrangement has the disadvantage that the light strikes and leaves the surfaces at an angle, and this angle must be the same for both surfaces, or the reading will be inaccurate. This necessitates an expensive construction. The modified form described in this specification comprises a rotating disc consisting of two or more sectors of translucent material separated by radial opaque films. The disc is illuminated at the sides, and observed on edge. Opaque covers are fixed to one side of each sector so that each is illuminated from one side only. Various modifications of this arrangement are described. Eight claims, eight figures.

11,460/08. **Supports for Metal Filaments.** BRITISH THOMSON-HOUSTON CO., and T. E. ROBERTSON. According to this invention, metal filaments, liable to contraction, and supported rigidly at one end of the pedestal and looped over hooks at the other end, are further supported by spiral metal springs fixed either to the middle of the pedestal or to the lamp bulb. As the filaments are drawn inwards or outwards at the centre by these springs, they will merely straighten somewhat on contracting. The lateral movement of the springs permits of unequal contraction of the two halves of the sections. Furthermore, hammering of the filaments on their supports at the tops of the loops during transit is prevented by these intermediate springs. Five claims, two figures.

15,370/08. **Limiting the Speed of Telephone Magnetos.** G. BESCHELBERGER. The object of the device described in this specification is automatically to uncouple the magneto of telephone apparatus when the speed exceeds a certain amount. It comprises an ordinary ball governor, which, when the speed attains a predetermined limit, causes the two halves of a tooth clutch to separate, and thus disengages the driving handle from the armature. Three claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: MOUL, 1,596/08; MIERTSCHKE, 13,100/08; KÖRTING & MATHIESONAKT.-GES., 17,421/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: TAYLOR [Storage-battery sub-stations on A.C. systems] 22,531/07; BROWNE & BAYLISS [Metal conduits for wiring] 6,631/08; SIEMENS BROTHERS & CO. (*Siemens & Halske Akt.-Ges.*) [Indication of faults on transmission systems] 15,898/08.

Dynamos, Motors, and Transformers: FELTEN & GUILLEAUME LAHMEYERWERKE AKT.-GES. [Constant current, varying voltage D.C. generator] 25,744/07; LOW [Ventilation of laminated iron cores] 8,997/08; BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitats-Ges.*) [Dynamo-electric machines] 11,161/08; SIEMENS BROTHERS DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*) [Speed regulation of machines] 14,134/08; BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitats-Ges.*) [Commutation devices] 18,460/08.

Electrometallurgy and Electrochemistry: JOHNSON (*Badische Anilin & Soda Fabrik*) [Production of titanium-nitrogen compounds] 1,824/08; EVANS (*Elektrochemische Werke*) [Production of electric discharge] 8,425/08; RUTHENBURG [Furnaces] 12,408/08; GIBBS [Electrolytic cells] 28,147/08.

Ignition, Electric: DOWN, AND TELEPHOS, LTD. [Gas Burners] 1,453/06; HAILWOOD [Miners' Lamps] 1,979/08; SOCIÉTÉ D'ELECTRICITÉ NILMELIOR [Explosion Engines] 24,241/08; BROWN AND ROSS [Internal Combustion Engines] 24,711/08; FIRM OF R. BOSCH [Magneto Apparatus] 28,548/08.

Incandescent Lamps: HOWARD, 2,727/08; POPE AND O'CONNELL [Supports for Filaments] 19,052/08; THOMPSON (*Von Inwold*) [Manufacture of Filaments] 19,659/08.

Instruments and Meters: GLEW [Timing and Recording Device for Electric Discharges] 7,261/08; KOEPSEL [Method of Electrically Transmitting Weak Movements] 18,258/08.

Storage Batteries: LAKE (*Clare*) 1,005/08; VAN RADEN & CO., AND METZ, 2,727/08; VAN RADEN & CO., ROBINSON, AND METZ [Manufacture of Battery Plates] 2,728/08.

Switches, Fuses, and Fittings: TAYLOR [Starter for Organ-blower Motor] 2,295/08; STATTER [Circuit Breakers] 6,568/08; BURNS, AND SYLVERLYTE ELECTRIC LAMP CO., LTD. [Lenses for Portable Lamps] 10,696/08; SIEMENS & HALSKE AKT.-GES. [Time-limit Relays] 15,742/09; LÜLING [Switches] 17,752/08.

Telephony and Telegraphy: DEAN [System of Telegraphy] 15,940/08; SCHILLING [Disinfection of Telephone Mouthpieces] 17,531/08; CREED AND COULSON [Telegraphic Apparatus] 23,834/08.

Traction: BAILEY [Trolley Heads] 19,357/08; SIEMENS BROTHERS & CO. (*Siemens & Halske Akt.-Ges.*) [Closed Circuit Signalling System] 22,409/08; CARSTENS [Signalling Apparatus] 24,052/08; MAYER [Trolley Wire Suspenders] 26,485/08.

Miscellaneous: HOOPER and HOOPER [Electrical socks] 12,987/08; ROSE and KENNEDY [Devices for locking railway carriage doors] 14,607/08; ROWE [Electromagnetic device for cushioning blows] 15,874/08; CASS [Fire alarms] 18,787/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

SIEMENS & HALSKE AKT.-GES.: [Electrolysis of aqueous saline solutions] 605/09; ZIPPLIES [Meters] 636/09; DELON [High-tension continuous-current generator] 1,070/09.

Expiring and Expired Patents

The following patent expires during the current week after a life of fourteen years:—

3,086 of Feb. 12th, 1895. **Keyboard Telegraph Transmitter.** H. H. LAKE. (*World Flash Co., U.S.A.*) This patent is for a keyboard for automatically transmitting the Morse signal for any letter, on the depression of the corresponding key. For every character there is a contact ring, and these are arranged side by side on, and concentric with, a toothed driving barrel. The contact rings are toothed at their inner peripheries, and the depression of a key causes the corresponding ring to engage with the driving barrel and to rotate. Brushes bear on the rings, and insulating pieces on the peripheries cause the making and breaking of the circuit at the proper intervals. On the completion of the signal the ring is disengaged from the driving barrel.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c. MERVYN J. O'GORMAN [Covering a stranded cable with a

Digitized by Google

lead sheath before applying the insulation] 21,170/01; A. SCHLATTER [Automatically switching in and out transformers in sub-stations as the load varies] 22,825/02; F. H. DE VEULLE [Cable terminal] 22,634/03.

Dynamos, Motors, and Transformers: BRITISH THOMSON-HOUSTON CO. (*A. L. Rohrer*) [Connecting leads to carbon brushes by copper-plating the brush and soldering a metal clip to the plated brush] 22,079/98; J. H. HINDLE [Ventilation of pole cores] 22,423/03; E. A. CARDAN (*General Electric Co., U.S.A.*) [Dynamo and motor design] 22,911/03, 22,912/03, and 22,913/03.

Ignition, Electric: E. S. BOWEN [Explosion-engines] 22,950/02. R. O. BEST and ACKROYD & BEST, LTD. [Miners' lamps] 23,021/02 and 23,022/02.

Instruments and Meters: G. L. ADDENBROOKE [Electrostatic instruments] 20,862/99; R. CHAUVIN and R. ARNOUX [Magneto speed-indicator] 22,795/03.

Switches, Fusings, and Fittings: BRITISH THOMSON-HOUSTON CO. (*H. G. Reist*) [Controller for A.C. induction motor] 24,131/97; BRITISH THOMSON-HOUSTON CO. (*E. M. Hewlett*) [Fuse-box with magnetic blow-out and renewable arcing tips] 13,615/00; A. P. ZANI [H.T. oil-switch in which the parts are covered with insulating material, except at the contacts, to prevent the arc spreading] 22,732/02.

Traction: A. J. BOULT (*N. A. Christensen*) [Automatic starting and stopping of compressor motors for brakes] 21,158/99.

Miscellaneous: W. H. WILSON [Winding coils] 22,443/03; J. A. STEVEN [Locking device for lifts] 22,507/03; O. IMRAY (*Siemens Schuckertwerke Ges.*) [Electric clocks] 22,664/03.

Restoration of Lapsed Patent

An Order was made on Feb. 2nd, under Section 20 of the Patents Act of 1907, restoring the patent granted to H. Chitty in April, 1902, and numbered 9,397 of 1902. The invention relates to the ventilation of electrical machines, and is for a method of construction in which each pole is divided into two parts by a radial passage extending right down the centre of the pole and parallel to the shaft. Passages in the pole, parallel to the plane of rotation, and coinciding with the armature ducts, are also provided, but these extend only to the length of the pole core, the air blown through these passages passes through the yoke by means of the above-mentioned radial passage which cuts them at right-angles. The radial passage is wedge-shaped, with its apex towards the armature.

Single-phase Railways in Switzerland.—According to the *Elektrotechnische Zeitschrift*, the special commission appointed by the Swiss Government to deal with the introduction of electric traction on the State railways has fixed the standard frequency for single-phase railways at 15 cycles per second. In cases where power is supplied from works generating at 40 or 50 cycles by means of frequency converters, the limiting values are to be 13·3 and 12·6 cycles per second.

Train Lighting in India.—In connection with the lighting of the trains on the Indian railways, the Railway Conference Association expressed the opinion that further experiments were necessary before the best system of lighting could be decided upon, and proposed that a committee should be formed from the locomotive and carriage superintendents and electrical engineers to consider the matter, and especially to standardise details. The Indian Railway Board approve of this suggestion, and also state that all new first- and second-class carriages shall in future be fitted with electric light and fans.

Glasgow Local Section, I.E.E.—At a meeting held in Glasgow on Tuesday last, Mr. W. W. Lackie read a short Paper in which he described some of the earlier experiments in electric traction. The author commenced by referring to the electro-magnetic engine driven by means of primary batteries, built by Robert Davidson, of Aberdeen, and tried by him on the Edinburgh and Glasgow Railway in 1842. In 1839, however, Prof. Jacobi, of St. Petersburg, had already propelled a boat carrying ten or twelve passengers by means of 64 Grove cells, and in the same year Davidson had exhibited an electric locomotive capable of carrying two persons. An illustrated description of the locomotive tried in 1842 and published at the time is given in Mr. Lackie's Paper. The battery consisted of 40 cells of iron and zinc plates in dilute sulphuric acid, and the total weight of the locomotive with passengers was about six tons. A speed of four miles was attained on the level.

Universal Electrical Directory, 1909.—The 1909 Universal Electrical Directory, published by our contemporary, *The Electrical Review*, has now been issued. As usual, it consists of four sections, viz., the British with 13,354 names; Colonial and General with 5,318 names; Continental with 7,952 names; and United States with 5,290 names, a total of 31,894, after a careful elimination of unimportant entries. Each section is sub-divided into an alphabetical and classified section, and in the case of the British, the additional geographical section of unquestioned use to travellers. The "Red" book is so familiar to the electrical industry that we need say no more than that it remains as excellent as ever.

WHAT IS "TRINIDAD BITUMEN"?

ORIGINALLY, all the bitumen employed for electrical purposes came from the bitumen or asphalt lake in Trinidad, or else from the surface of the land surrounding the lake. The lake bitumen was found to be particularly suitable for electrical purposes, such as the "solid" system of cable laying, and the filling-in of junction boxes, &c., for it contains a large proportion of mineral matter, which makes it more suitable than chemically pure bitumen for the purpose. A preliminary refinement is first carried out before the material is shipped: this consists of the addition of a small percentage of bituminous oil as a flux, and the removal of some of the coarser impurities, such as pieces of stone, wood, &c., and the material thus refined is known to the trade as bitumen "épurée." A further refinement and an admixture of a small amount of shale oil as a flux is, we believe, usually carried out before use, after the arrival of the material in this country.

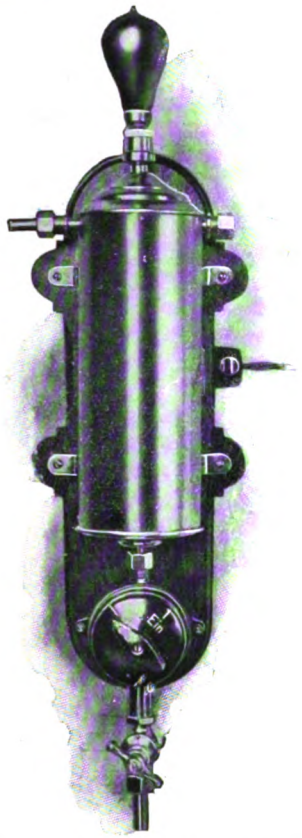
About ten years ago some mines were discovered in Trinidad in which an almost pure bitumen was found, and this was given the name "manjack." In its natural state it is far too brittle for the electrical engineering purposes above mentioned, but, after the addition of a considerable proportion of crude bituminous oil—say, from 10 to 15 per cent.—and an admixture of gypsum or other similar mineral matter, it has been employed largely for the same purposes as the natural lake bitumen.

Messrs. Prévité, who supply the bitumen from the lake, have undertaken to give the Callender Cable and Construction Co. the call of all the bitumen required for electrical purposes, and it is made a condition of the supply through the various agents and brokers that no other firm is to be furnished with lake bitumen for such use. On the other hand, the firm of W. H. Keys are supplying and advertising "genuine Trinidad bitumen," for electrical purposes, and they are being prosecuted at the Thames Police Court, before Mr. Chester Jones, under the Merchandise Marks Act, for supplying material under the "false trade description" of "Trinidad bitumen." The case is still proceeding. Two leading counsel have been retained, Mr. Bodkin for the prosecution, and Mr. Vachell, K.C., for the defence, and a succession of expert witnesses, including Mr. Tom Callender and Mr. Blount, have already been called.

From the evidence it appears that Mr. W. H. Keys has supplied two grades of bituminous mixtures as "Trinidad bitumen." He has explained the process of preparation, which is, roughly, as follows:—"Manjack" is first mixed with between 10 and 15 per cent. of crude bituminous oil to produce what he terms "Standard A." One of the two preparations, known as "Keys No. 1," contains 60 per cent. of "Standard A" and 40 per cent. of the "épurée" lake bitumen. In the second, known as "Keys No. 3," it appears that no lake bitumen is employed, but a proportion of gypsum or other mineral matter is added to the Standard A with the object of making the mixture suitable for electrical purposes, and that this proportion is varied according to the use to which the mixture is to be put. It is acknowledged on both sides that the former mixture, "Keys No. 1," at any rate, contains actually a larger proportion of pure bitumen than the natural lake bitumen, and that all the bitumen in it has been imported from Trinidad, but the prosecution argue that the description "Trinidad bitumen" implies either the natural land or the natural lake bitumen, and that this meaning is generally accepted in the trade. There are other bitumen deposits in Cuba, Nigeria, Mexico, and elsewhere, but these are said to be inferior for electrical purposes.

In the course of the evidence it was also elicited that Messrs. Crompton and Co. have used large amounts of Mr. Keys's bitumen mixture for electrical purposes.

CATALOGUES AND PAMPHLETS RECEIVED



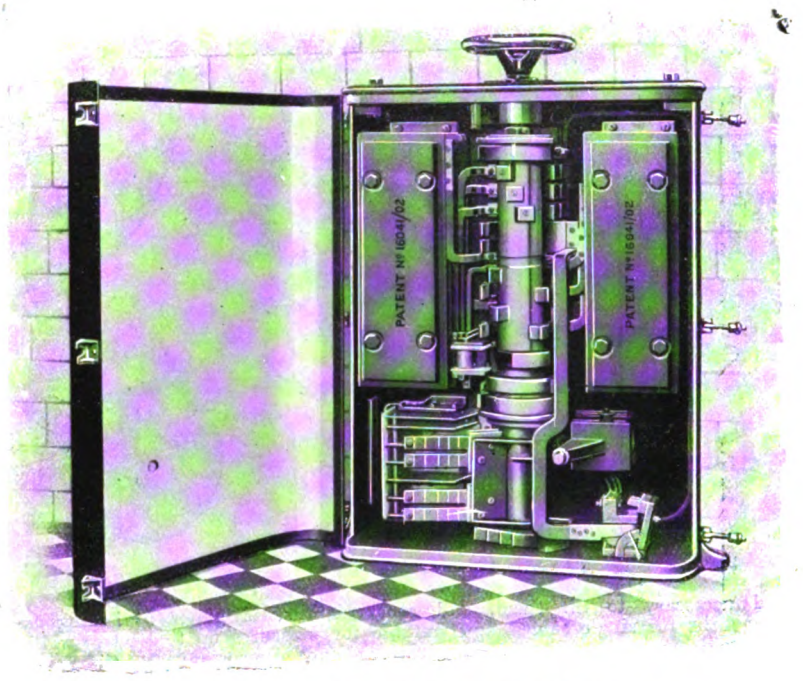
[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

OSRAM LAMPS.—A second edition of their Osram lamp list has been issued by the General Electric Co., Ltd., of 71 Queen Victoria Street, London, E.C. It has now been increased to 18 pages, and contains one or two new shapes and voltages, *e.g.*, the 50-volt and the 25-volt round bulb, as well as higher voltages and c.p. up to 400, with latest prices. The list also contains particulars of a portable cost indicator, which has been designed to enable contractors to demonstrate to their customers the saving which can be effected by the use of "Osram" lamps. This is contained in a compact case with leather handles, the scale being calibrated from 6d. to 4s. 6d. divided

Digitized by Google

into pence, for showing the cost per 100 hours of burning at a fixed price per unit and constant voltage. The standard ranges are for 3d., 4d., 5d., and 6d. per unit, and they can be supplied for 100/110 volts up to 240/250 volts.

ELECTRIC WATER-HEATER.—The "Express" electric water-heater is described in a leaflet to hand from the Electrical Co., of 121 to 125 Charing Cross Road, and is illustrated below. The apparatus consists of a number of tubes in which the water circulates and which are electrically heated. The cold water enters at the bottom, and leaves by the tube on the left, just below the lamp. The water-tap is automatically closed or opened when the switch is opened or closed as the case may be, thus ensuring that the current is only on while water is flowing, thereby preventing burning out of the coil. If the tap at the bottom is to the left the water is heated to 110° F. By turning the tap to the right more water leaves the outlet, but it is then at a lower temperature than 110° F.; a red lamp is fixed to the apparatus to show when current is on. When the plug is put into hole marked "high," the apparatus takes six amperes, whereas when put into hole marked "low" it only takes 3·5 amperes. The holes are not seen in the illustration. The apparatus can be used on either continuous or alternating current.



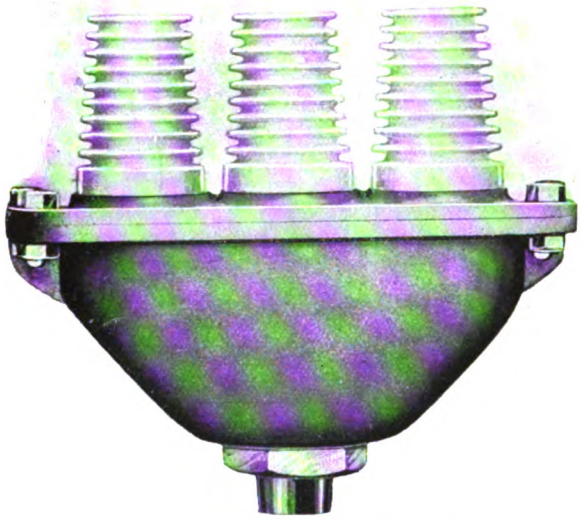
The Electrical Co.'s "Express" Water-heater.

TANTALUM LAMPS.—A useful new catalogue of tantalum lamps has been issued by Messrs. Siemens Brothers' Dynamo Works. Illustrations are given showing the appearance of the lamps with the various sizes of pear-shaped and spherical bulbs which have been standardised. The sizes at present on the market include the small lamps for 24 to 25 and 32 to 35 volts for 5, 10, 16, and 25 c.p.; the useful 16-c.p. lamp for voltages up to 130 volts, and the larger 25-, 32,- and 50-c.p. lamps made for voltages up to 160 volts. The list is conveniently arranged and shows clearly for what voltages the lamps of particular candle-power are most suitable in the case of alternating, as well as continuous-current circuits. Among other new features of the catalogue are an illustration showing tantalum lamps in use for train lighting on a "tube" railway, and particulars regarding coloured varnishes and obscuring lacquer. With the exception of 16-c.p. lamps for 100-volt alternating-current, all the lamps are listed at an efficiency of 1·7 watts per British candle. The D.C. 16-c.p. lamps are supplied for this efficiency, but when 100-volt lamps of this candle-power are required for alternating current an efficiency of 2·2 watts per candle-power should be specified.

TELEGRAPH AND TELEPHONE INSULATORS AND BOLTS.—The British Insulated and Helsby Cables, Ltd., of Helsby, near Warrington, have issued a new catalogue of insulators and bolts. It covers almost every type of insulator, and no engineer engaged in overhead line construction work should be without a copy of this book. The firm only stock white porcelain insulators, and not those of brown porcelain or brown stoneware. They recommend the pattern with an internal screw thread so that it can be used with a screwed bolt. This has two advantages; first, that the insulator can be renewed without removing the bolt from the arm, and secondly, it is more convenient and economical to be able to pack the porcelain and ironware separately for transit. At the end of the catalogue are extremely clear and well-illustrated instructions for jointing and binding.

MOTOR STARTERS.—We have received a leaflet from Messrs. A. Reyrolle & Co., Ltd., of Hebburn-on-Tyne, in which their latest pattern of drum-type starter for continuous-current motors is described. The accompanying figure illustrates one of these starters. In this figure the magnetic blow-out, no-voltage release, over-load release, and double-pole, double-break circuit breaker are all clearly visible. The starting wheel cannot rest in an intermediate position, and is so interlocked with the no-voltage release magnet that the armature circuit is opened immediately if the field circuit is broken. All these starters are fitted with the firm's patent "current growing" resistances, which allows the current to gradually increase until sufficient to start the motor at all loads, whilst the hand-wheel is held at the first stop. Gas-tight cases are supplied for starters to be used in mines. Full particulars and dimensions of all sizes from 15 to 100 h.p. are given in this leaflet.

Reyrolle Drum Type Starter.



AEGMA LAMPS.—A leaflet from the lamp department of the Electrical Company, 121 Charing Cross Road, calls attention to the higher voltage "Aegma" metal lamps which are now made for 50 and 100 c.p. to run singly on 200- and 250-volt circuits, with an efficiency of 1·2 watts per c.p. The filaments are stated to be in every way equal to the latest pattern of the firm's low-voltage lamp.

THERMOMETERS AND PYROMETERS.—A number of patterns of indicating and recording thermometers are described in a pamphlet received from Engineering Supplies, Ltd., of 28 Victoria Street, London, S.W. The essential part of these thermometers, which are known as Steinle's steel-mercury thermometers, is a steel spiral spring, consisting of a solid drawn steel tube, with thin walls rolled flat until the sides meet within 1/100 in., and coiled. This spring is fixed to a container, and the whole is filled with mercury. When the mercury expands the spring uncoils slightly, and this rotary motion is transferred by a multiplying gear to a dial hand. As the mercury is always under pressure, it can be heated beyond its boiling point. Temperatures up to 950° Fahr. can be registered. Instruments fitted with electric alarm bells for minimum and maximum temperatures, and recording instruments for use, for example, for recording the temperature of superheated steam in central stations, are described and illustrated. These latter can be fitted with electrical recording apparatus, where it is required to separate the recording instrument from the thermometer. Graphite pyrometers for measuring temperatures above 950° Fahr., and depending for their action on the relative expansion of iron and graphite, are also described.

Digitized by Google

WIRES AND CABLES.—A new edition of the General Electric Co.'s catalogue of wires and cables is to hand. In addition to full lists of pure and vulcanised rubber-covered cables and wires of the company's "Omega" and "Alpha" brands—the latter of which is guaranteed equal in quality to the C.M.A. standards—the catalogue contains a quantity of useful tables and information relating to wires and cables and particulars of fuse wires, resistance wires, cable connectors, flexible instrument wires, bell wires, telephone cables, together with wooden casing, porcelain insulators, tools, &c.

CABLE ACCESSORIES.—A pamphlet from Messrs. A. Reyrolle & Co., Ltd., of Hebburn-on-Tyne, relates to the various sizes and patterns of dividing boxes manufactured by them. The accompanying illustration shows one pattern suitable for three-core cables and pressures up to 3,000 volts. Full information with regard to these boxes, including the weight of compound necessary to fill them, and other details, is given. Sealing bells for single cables, and suitable for pressures up to 12,000 volts, are also listed. Illustrations and dimensioned drawings of these boxes are given in the pamphlet.

REYROLLE DIVIDING BOX.

ALUMINIUM LAMPHOLDERS.—A new use has been found for aluminium, in the construction of the electric lampholder described in a leaflet to hand from the Sun Electrical Co., Ltd., of 118-120 Charing Cross Road, London, W.C. This is offered at a price below that of a similar article in brass, and is essentially suitable for outside work, and for situations which are damp and exposed to fumes, owing to its non-corroding qualities.

"BELL" INTERCOMMUNICATION TELEPHONES.—The Sun Electrical Co., of 118-120 Charing Cross Road, London, W.C., have designed the "Bell" intercommunication telephone set to meet the demand for an efficient office telephone at a moderate price. A simple selecting switch is employed, which gives a positive contact at each point. The battery reversing gear on the home line switch contact (formerly necessary on direct working inter-communication telephones) has been eliminated; the line selector, attached to a revolvable transmitter, is provided with a particularly simple step-by-step movement, and is positive in action. When speaking, only the battery of the station called is in use, thus minimising the amount of "cross-talk" by induction, owing to the low E.M.F. on the line.

"ECONO" LAMPS.—A new leaflet from S. Zossenheim, of 33 Bedford Place, London, W.C., gives some particulars of the "Econo" metal filament lamp, which can be obtained for various pressures between 35 and 250 volts, with candle-powers of from 10 to 100. We notice that a reduction in the price of the 200- to 250-volt lamps has been made. The specific consumption is stated to be about one watt per candle. A 250-volt 40 candle-power lamp is listed.

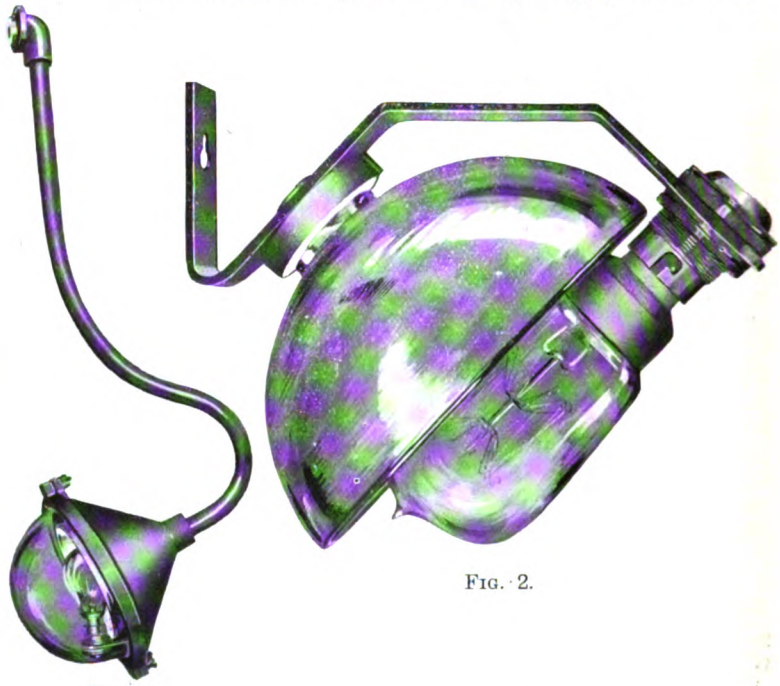
CONTINUOUS-CURRENT MOTORS.—The J.-L. Manufacturing Co., of Johnson-Lundell Works, Southall, have issued a preliminary list of their patent laminated field motors pending the completion of their complete illustrated catalogue, in which these motors will be dealt with together with a series of dynamos of the firm's manufacture. The principal points of the design of these motors, which have some important features of originality, were dealt with in ELECTRICAL ENGINEERING, Vol. II., page 488.

NEW SHOP LIGHTING FITTINGS

THE accompanying illustrations represent two out of a series of new designs of shop lighting fittings specially designed for metal filament lamps which the Reason Manufacturing Co., of Brighton, have recently introduced.

The special point about the fitting shown in Fig. 1 is the silvered glass reflector, which is placed at the back of the lamp, and which enormously increases its effective candle-power, and, at the same time, diffuses the light in a most satisfactory manner. The globe is attached to a strong cast-iron ring, and can readily be removed for cleaning and renewal purposes. Ornamental scroll-work can be added at a very slight additional cost, if desired.

Fig. 2 shows an effective interior window fitting. The reflector used is of the firm's patent silvered glass type, and is ever-



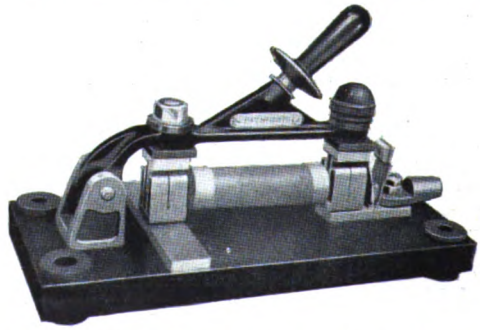


FIG. 1.

FIG. 2.

lasting as regards the silvering, this being protected between two walls of glass and sealed up, so as to be contained in an air-tight and damp-proof compartment. They are also strongly made, and not liable to mechanical breakage except with the roughest handling.

A COMBINED KNIFE SWITCH AND FUSE

A RECENT addition to the long series of switch fuses manufactured by British Insulated & Helsby Cables, Ltd., is shown in the accompanying illustrations. The apparatus, which is manufactured under Hornby's patent, is more truly a switch fuse than the ordinary removable tubular and other fuses with or without handles, as it is more truly a switch as well as a fuse. It is, in fact, a combination of a well-made knife switch and an enclosed fuse, and is particularly suitable for use in sub-stations, and in cases where the available space is limited. As will be seen from the illustration, the switch

blades also form the terminal clips for the enclosed fuse. The switch blades are securely fastened to, and well insulated from, the substantial metal lever which carries the switch handle. When the switch is in the "off" position the blades are quite clear of the spring contacts, and the fuse can be readily withdrawn or replaced without danger of shock. The switch is fitted with a carbon break.

REVOCATION OF A FLAME ARC LAMP PATENT

THE first electrical cases under the revocation clause (Section 27) of the new Patents Act have come before the Comptroller, and we are able to announce the decision in one of the two cases. The patents in question are No. 18,786 of 1902, and No. 23,606 of 1902, which, it is contended, have not been adequately worked in this country.

The first of the two patents, upon which the Comptroller has just made his decision revoking the patent, is in the name of H. Bremer, and relates to the feeding of the carbons in flame arc lamps of the converging carbon pattern. The patent —which, by the way, was amended in December, 1907, when one of the claims was struck out and a disclaiming note added—describes mechanism for the purpose of obtaining a lateral movement of the point of one or both carbons in addition to the downward feeding motion. In a previous lamp patented by Bremer, converging carbons were fed through an opening in the bottom plate of the lamp, and in the action of feeding both carbons moved downwards simultaneously and approached one another. The present patent is for an additional device for giving one or both carbons a swinging lateral movement independent of that due to the feed.

Two alternative mechanisms are described in the specification. The first consists of an arm or lever, one extremity of which bears against the lower end of one carbon. An armature attached to the other end is attracted by an electro-magnet connected in shunt across the arc, and this end also holds the detent, which engages with a star-wheel geared to the feeding-cord drum. If the arc lengthens, the armature is attracted to the magnet, and the swinging carbon pushed towards the other carbon, and this action is continued until the armature has moved to such a point that the star-wheel is released. Feeding then takes place. The second mechanism described is only a modification of the above, in which the swinging carbon is moved by means of a loose collar near its burning end. The movement of this collar is controlled by a vertical shaft which is given a rotary motion by means of the differential action of shunt and series coils.

The single claim attached to this specification is as follows:—

An arc lamp having downwardly pointing electrodes and provided with both downward and horizontal feed mechanism, so arranged that a certain amount of operation of the horizontal feed mechanism takes place before the downward feed mechanism is permitted to operate, subject to the disclaiming note.

The disclaiming note reads as follows:—

The lamps to which my invention applies are of the type in which the current is supplied to the electrodes through electrode-holders, in which the upper ends of the electrodes are firmly clipped, and which are capable of being lowered simultaneously through the same distance, and about one of which the corresponding electrode can swing under the action of a device acting near its lower end, and I limit my claim to lamps of this description.

This patent is owned by the British Westinghouse Electric & Manufacturing Co., Ltd., and the Union Electric Co., Ltd. are licensees, both firms selling in this country arc lamps under the patent. The present application was made by Mr. G. Braulik, who petitioned that the patent should be revoked under Clause 27 of the Patents Act, 1907, on the ground that the patented article was manufactured mainly outside the United Kingdom. In response to this, it was declared that the lamp had been manufactured to a large extent by the British Westinghouse Co. at their Trafford Park Works in the years 1905–1908. Up to October 23rd, 1908, 1,308 lamps had been manufactured, of which 274 remained unsold. It was maintained that as the company had manufactured as many lamps as it could sell, manufacture was carried on to an adequate extent in the United Kingdom, and that the sale of the lamp had been materially interfered with by the "unauthorised importation" of infringing lamps. Other evidence showed, however, that a much larger number of lamps manufactured in accordance with the patent by Messrs. Körting & Mathiesen, under license, had been sold by the Union Electric Co., the agents of the latter firm in this country. The number of lamps so imported during the years from 1906–1908 amounted to 9,856.

In his decision, the Comptroller emphasises the point that the infringement of which complaint had been made, consisted of the *importation* of infringing lamps and not the *manufacture* in this country of infringing lamps. The Comptroller is satisfied that the allegation that the patented article is manufactured mainly outside the United Kingdom is correct. Continuing his statement, the Comptroller states that the question then arises whether the patentees have proved that the lamp is manufactured to an adequate extent in the United Kingdom, and, if not, whether they have given satisfactory reasons why it is not so manufactured. The Westinghouse Co.'s counsel argued, says the Comptroller, that a patentee is entitled to import as many patented articles as he likes into this country, provided he satisfies the law as to adequate working, and that he satisfies the law as to adequate working, notwithstanding his importation, if his sale and manufacture in England is to the best of his ability, whatever such ability may be. That is to say, if he grants, as has been done in this case, a license to a licensee, who does not manufacture the patented article in this country, but imports it in very large quantities, he himself manufactures the patented article to an adequate extent in this country, however small his manufacture here may be, provided that it is not smaller than the margin between the demand for the article and the number of the articles imported. It is obvious, says the Comptroller, that if any such interpretation is to be placed on the words "adequate extent," the section will be inoperative in any case in which a foreign manufacturer can persuade the proprietor of a patent that it will pay him better to take a royalty on every lamp imported, whilst he himself manfactures here on an infinitesimal scale, than to manufacture the patented article himself in this country to any substantial extent.

The interpretation which the Comptroller places on the words "to an adequate extent" is "*to such an extent as will substantially satisfy the demand in this country, even if no importation take place.*"

Having decided that the patented article is manufactured mainly outside the United Kingdom, and that it is not manufactured in this country to an adequate extent, it only remained, therefore, for the Comptroller to decide whether the Westinghouse Co. had given satisfactory reasons for their failure to manufacture to a greater extent. The reasons given were that they had been unfortunate enough to grant licences to the German company until January 1st, 1911, and they could, therefore, not prevent the licensees from importing as many of their "excellent" lamps as they please. This reason, however, is not regarded as satisfactory by the Comptroller, for, he says, it does not explain why the German company did not manufacture their lamps in the United Kingdom.

Mr. Eck, Secretary and Chief Engineer of the Union Electric Co., admits that his German house are the premier firm of arc lamp manufacturers in the world, and that they have no present intention of manufac-

Digitized by Google

turing the patented article in this country, and no evidence was forthcoming to explain satisfactorily why they had not. No evidence was given to prove that they could not, under their licence, manufacture their lamps in this country and sell them at a profit at their present prices. The fact that they could make them in Germany at a larger profit would not, if proved, constitute a satisfactory reason, in the Comptroller's opinion, for not manufacturing them in this country.

On the evidence before him, the Comptroller therefore comes to the conclusion that the patented article has not been manufactured to an adequate extent in the United Kingdom, and that the reasons given by the patentees why it had not been so manufactured were far from satisfactory. He therefore decided, subject to an appeal to the Court, to revoke the patent forthwith, and he ordered the patentees to pay to the applicant the sum of 75 guineas in respect of his costs.

The other patent for the revocation of which application has been made is No. 23,606 of 1902, and was granted to P. Högner, of the firm of H. Körting & Mathiesen, of Leipzig, whose agents in this country are the Union Electric Company. This patent also refers to flame arc lamps of the converging carbon type, and is for various constructions in which the regulating solenoids are employed solely for the purpose of controlling the length of the arc, the feeding forward of the carbons being effected by independent means. Twelve different designs are described and illustrated in the specification. In most of these the feeding is effected by gravity, but two of the examples have a forced feed actuated electrically. In the case of the gravity feeding lamps, a star-wheel geared to the cord-drum is released by a detent when the regulating mechanism can no longer shorten the arc, as in the patent described above. The detent in this case, however, is fixed to the sleeve containing the swinging carbon. This sleeve is pivotted, and is swung by means of the solenoids. In some examples the series solenoid is replaced by a spring. A collar, or slide, surrounding the carbon near its burning end is provided in some of the designs shown, and the movement of this collar is controlled by the differential action of the shunt and series coils. In another example the relative lateral movement of the carbons is effected by pivotting both sleeves, and hanging the guide-plate or economiser from an arm controlled by the regulating solenoids. Finally, different patterns of sliding contacts for conducting the current to the carbons close to the arc itself are described. There are eight claims to this patent.

The first is as follows :—An arc lamp with electrodes placed side by side and longitudinally displaceable, and having electromagnets excited according to the electrical conditions of the arc, and constantly regulating the consumption of the carbons, the distinguishing feature being that the axial movement is controlled by the lateral movement and effected compulsorily by suitable means.

The second claim is for an arc lamp according to Claim 1, the distinguishing feature of which is that the feed mechanism producing the forward movement of the carbon is so fixed that it can take no part in the lateral movements or oscillations of the electrodes.

The third claim is for an arc lamp according to Claim 1, the distinguishing feature of which is that the electrodes are arranged beneath the frame plate and are pivotally suspended at the upper ends.

Claim 4 is for an arc lamp of the type referred to in Claim 3, in which the lateral movement of the carbons is caused by a vertical movement of the guide-plate through which they pass. The vertical movement of the guide-plate is effected by the differential action of the shunt and series coils.

Claim 5 is for an arc lamp according to Claim 1, the distinguishing feature of which is that the electrodes receive the current through carbon-holders or suitable sliding contacts in proximity to the arc.

Claims 6 and 7 describe two alternative forms for these sliding contacts.

Claim 8 is as follows : An arc lamp according to Claim 1, the distinguishing feature being that the oscillation axis of the movable slide mechanism coincides with that part of the cord or chain pulley circumference where the running-down chain leaves the running-down pulley.

In this case also, Mr. G. Braulik is the petitioner for the revocation of the patent.

LOCAL NOTES

ABERDARE: *Electric Lighting.*—A Local Government Board inquiry was held last week into an application of the Council for sanction to borrow £17,000 for the purposes of an electric lighting scheme. There was a good deal of opposition from colliery companies and the Aberdare Gas Co. Mr. Stephen Sellon, who has advised the Council in the matter, estimated a revenue of £3,083, and total working expenses amounting to £1,551. The inquiry was adjourned *sine die*.

ABER VALLEY: *Electricity Supply.*—Messrs. Preece & Cardew have advised the Urban District Council that the results of their canvass of the district have not been sufficiently satisfactory to justify the Council applying for an electric lighting provisional order. The matter is to be further discussed with the consulting engineers.

BATH: *The Electricity Bill.*—At the meeting of the Rural District Council last week attention was drawn to a clause in the Bath and District Electricity Bill which stated that, in the event of an extension of the City boundaries, the area of supply should be extended also. It has been decided to petition against the Bill. The Bill has been reported for first reading by the Examiners of Standing Orders.

The Electricity Works.—The recommendation of the Electricity Committee that, owing to the action of the Board of Trade, the negotiations with Mr. Shenk for the purchase of the electricity works should be abandoned, given on page 108 of our last issue, has been passed by the Corporation.

BECKENHAM: *Insurance of Plant.*—The Electricity Committee have taken out a floating policy with the British Engine & Boiler Insurance Co. insuring the six engines and dynamos at the electricity station against breakdown at a maximum sum of £600, the annual premium being £72, and the auxiliary machinery to a maximum sum of £475 at an annual premium of 17 guineas.

BOURNEMOUTH: *The Tramway Administration.*—A special Committee of the Corporation has reported upon the recommendation of Mr. J. B. Hamilton on the working and management of the tramways undertaking. We gave this report at length in our issue of January 14th, page 36. The chief point dealt with was the question of the appointments recommended in the report in question, and, as a result, it was decided to appoint a general manager on the lines laid down by Mr. Hamilton, and it was recommended that Mr. Barber, the present engineer and traffic manager, should be offered the post. Mr. Hamilton's report also necessitated the abolition of the post now held by Mr. I. Bulfin, the Electrical Engineer. Arising out of the Committee's investigations and Mr. Hamilton's report, the engineer and traffic manager, Mr. Barber, sent a letter to the Corporation asking them to put the post up for competition, when he would be pleased to send in an application, a course of action which he said he felt bound to take owing to the Committee's report involving the replacement of his colleague, Mr. Bulfin, by an assistant electrical engineer at £200 per year. Mr. Bulfin has also tendered his resignation. This course has been adopted.

BURY: *Supply Outside Boundaries.*—The Lancashire Electric Power Co. have asked the Corporation to make certain amendments in their Bill in reference to the supply of electrical energy in bulk to neighbouring authorities. The Town Clerk has replied that the Corporation already have powers to supply electrical energy in this manner, and that in the present Bill these were only consolidated.

CARDIFF: *L. G. B. and New Loan.*—The Finance Committee of the Corporation have passed the resolutions put forward by the Chairman of that Committee in order to give effect to the recent criticisms of the Local Government Board Inspector concerning the financial position of the electricity undertaking. These resolutions were given in full on page 97 of our issue of January 28th.

Electricity Supply.—Negotiations are being carried on between Sir William Lewis and the Electricity Committee in relation to the supply of electricity to the Bute Docks. A committee has been appointed together with the engineer to carry the matter on.

COLCHESTER: *Tramway Fares.*—The Colchester Town Council has decided to revert to the old system of tramway

Digitized by Google

fares, owing to the public having boycotted the cars since the higher rates were introduced about two months ago.

Overhead Wires.—The Board of Trade has declined to give its consent to the erection of an overhead feeder cable to the Hythe.

Supply to Outlying Districts.—The Borough Electrical Engineer is to visit Chesterfield to inspect the method adopted for supplying electrical energy to outlying districts by means of the overhead tramway wires. A full description of this was given in ELECTRICAL ENGINEERING, Vol. I., p. 1,078, and it was estimated that the cost of such a scheme for the purpose at Colchester would be £485.

DUBLIN: *Electric Lighting Undertaking.*—The City Treasurer and City Accountant have prepared a report upon the position of the electricity undertaking down to March 31st, 1908. In this they have instituted a general comparison with the results of similar undertakings in other cities, and endeavoured to arrive at an estimate of future prospects. The following is a brief recapitulation of some of the suggestions :—I. Certain additional charges should, in future, be debited to the electricity revenue account, viz. :—(*a*) Proportions of salaries of permanent officials hitherto charged to capital account; (*b*) cost of water supply; (*c*) proportions of salaries of some officials of other departments, &c.; (*d*) renewals of meters. II. Provision should be made by way of sinking fund for a reserve to meet part costs of renewals of machinery, &c. III. Provision should be made to earn a moderate margin of profit, which should be available to eliminate, gradually, the balance to debit of rates account, as well as the cash overdraft, and eventually to recoup the rates the expenditure thereout in previous years. IV. To meet the additional charges and provisions above referred to—owing to the great reduction in the cost of lighting effected by use of metallic filament lamps—an increase of prices is necessitated :—(*a*) A minimum average increase of ½d. per unit for private lighting is required for the three years to end March, 1912. Taking the coming year alone, a higher figure is required, and the advisability of an increase of ¾d. per unit should be carefully weighed by the Lighting Committee, who, at the same time should deal with (*b*) the question of a general simplification and readjustment of prices. They should, further, reconsider (*c*) the proposed reduction of power rate to 1¼d., (*d*) the allowance of 25 per cent. discount for twelve months to new consumers, and (*e*) the allowance of ¼d. per unit or 7½ per cent. discount where power and lighting supplies are combined. V. With regard to expenditure, the utmost care should be exercised in connection with (*a*) purchase of coal, (*b*) extensions of mains, (*c*) extensions of public arc lighting. VI. It would be desirable to exempt the Lighting Committee from the regulation governing the constitution of other committees, and provide for greater continuity in the service of members on it.

EAST HAM: *Supply by West Ham.*—The Electric Lighting Committee report having received a letter from the West Ham Town Council stating that they were in receipt of an application from a large firm of manufacturers at Silvertown in East Ham for a supply of current for power purposes from the West Ham undertaking. West Ham asked whether, as they understand East Ham are not contemplating giving a supply in the area south of the docks, any objection would be raised to West Ham carrying their cables through and giving a supply to such applicants. The East Ham Electric Lighting Committee, having fully considered the matter, have decided in favour of no objection being offered to West Ham doing as proposed, provided they agree to pay the nominal rental of £10 per annum and subject to their entering into an agreement.

ECCLES: *Tramway Running Powers.*—The Council has resolved to proceed with its action against the South Lancashire Tramways Co., unless the Salford Corporation agrees to apply in writing for the consent of the Council to the cars of the company running in the borough, or agrees to the terms suggested at the last meeting of the General Purposes Committee.

EDINBURGH: *Electric Traction.*—The Borough Engineer has been asked to report upon the possibility of using the trackless trolley system in the suburban districts.

Water Power.—The engineers of the electricity department have been asked to report on the sources of water power in Edinburgh which might be available for the purposes of the electricity undertaking.

FOLKESTONE: *Tramways Co. and Council.*—As a result of communications that have taken place between the Council and Messrs. Deacon & Co. (on behalf of the Folkestone, Sandgate & Hythe Tramways Co.), in which they state that the company, after the expenditure of a great deal of time and money upon the Dolter surface-contact system, have been forced to the conclusion that it is not, and cannot be made, suitable for electric traction in this country, the Town Clerk has informed the committee that Section 78 (2) (*b*) of the Folkestone, Sandgate, and Hythe Tramways Act, 1906, provides that if, in the opinion of the Corporation, or of an arbitrator, the Dolter system has not been working satisfactorily, then the system of traction is to be other than the overhead, and as approved by the Corporation or arbitrator. Messrs. Deacon & Co. are accordingly to be informed that, from the information that they have supplied, the system to be adopted for the Folkestone tramways should be determined upon in accordance with the provisions of Section 78 of the Act.

GATESHEAD: *Local Bills.*—The Council has decided to petition against the Bill of the County of Durham Electric Supply Co., and also that of the Gateshead & District Tramways Co.

HALIFAX: *Advertising on Tramway Posts.*—The Tramways Committee have agreed, as an experiment, to allow a London company to fix on one of the tramway posts an electrically lighted advertisement. The Company wish to rent every alternate post in Halifax, their offer being 10s. per annum per post, in addition to paying for the energy used in the signs. There are between 3,000 and 4,000 tramway posts in Halifax.

ILFORD: *Electricity Works.*—A report has been prepared by the Electrical Engineer stating that it is desirable to take into consideration the question of future extensions of the existing electricity works or the removal of the power-house to a site on the sewage works at Creeksworth. The Electricity and Tramways Committee have decided that no action be taken with regard to the removal of the works at the present time.

LEEDS: *Tramway Brakes.*—At the last meeting of the City Council a recommendation by the Tramways Committee that an order be placed with the Electro-mechanical Brake & Engineering Co., Ltd., of West Bromwich, for thirty mechanical and magnetic track brakes was protested against. It was claimed that Mr. J. B. Hamilton, the Tramways Manager, held 1,510 shares in the Company and was also a director, and, further, as one of the patentees, he would get £4 10s. per brake manufactured by the Company, so that on the present proposal he would receive a royalty of £135. The brake in question is the Maley brake, which was fully described in ELECTRICAL ENGINEERING, Vol. III., p. 851. On behalf of Mr. Hamilton, it was stated that a resolution had been passed last year by the Council agreeing to pay the patent fees in respect of this brake not exceeding £20, upon the condition that any brakes required by the Corporation should be free of royalty charges; therefore no royalty fees would be paid on the brakes now under discussion. It was further stated that, knowing the interest Mr. Hamilton had in this Company, the members of the Tramway Committee would take greater care than usual to satisfy themselves that the brake was the best brake to be obtained. In the course of further discussion it was stated that Mr. Hamilton had joined the Board of the Company with the permission of the Corporation, but that immediately objection was taken to his position in connection with the present proposal he had sent in his resignation as a director, and, further, had taken immediate steps to dispose of his interest in the business.

LONDON: *Kensington.*—Mr. Flint, the architect to the Guardians, has been authorised to estimate for installing the electric light in the clerk's and relief offices.

London County Council: Tramways.—The Highways Committee recommend the purchase of a portion of the Harrow Road and Paddington tramways from the Metropolitan Electric Tramways, Ltd., for £40,000. This amount, however, does not include the expenditure which will be incurred in the acquisition of a certain forecourt in Harrow Road which the Company is under obligation to acquire in order that it may be added to the roadway. The Company will, however, continue the proceedings for the acquisition of this property. It is not proposed that the Council shall acquire from the Company any cars or car-shed accommodation, but the sum mentioned above includes the overhead equipment and cables so far as they are applicable to this section of the tramways.

The Highways Committee have reported that the sanction for the expenditure of £10,000 upon the construction and equipment of tramways granted by the Council's Money Act of 1908 has fallen short of the required amount owing to other work having been put in hand by £35 000, and they recommend that application should be made for the Treasury's sanction for borrowing this sum.

The Highways Committee have had under consideration the question of providing special supplemental mechanical attachments to the magnetic brakes on cars operating upon hilly routes of the Council's tramways. This matter has been discussed in consequence of the reports of the Brake Committees of the two tramway Associations, and it is proposed that a sum of £[illegible] be expended in this connection.

It is recommended by the Highways Committee that the tramway route from Holloway Road to Upper Street, Islington, via Liverpool Road should be discontinued owing to the very poor traffic returns. Liverpool Road is for the greater part of its length almost parallel with Upper Street, Islington, and Caledonian Road on the east and west respectively, and is connected with these streets by numerous small side streets. As there is a frequent service of electric cars both along Upper Street, Islington, and Caledonian Road, it is thought unnecessary that any service should in future be run along Liverpool Road.

Hammersmith: The Workhouse.—A report has been prepared dealing with the capital expenditure upon the Hammersmith Workhouse, which was the subject of a lengthy Local Government Board inquiry in 1907 (ELECTRICAL ENGINEERING, Vol. I., p. 974). From this it appears that the electric light installation cost £7,593.

Islington: Accident at Electricity Works.—The inquest concerning the death of a labourer who fell into an unprotected pit of hot water at the Borough Council's electricity works was

Digitized by Google

concluded last week, the jury returning a verdict that there had been carelessness on the part of the officials of the electricity works in not protecting the pit and warning the employees of the danger.

Paddington: Tramways.—Negotiations have been concluded between the Borough Council and the Metropolitan Electric Tramways, Ltd., for the Company to pay £4,000 of the £4,500 expended by the Borough Council in widening Pickford's Corner, Harrow Road, for the electrification of the Harrow Road and Paddington Tramways owned by the Company.

MIDDLESBROUGH: *Claim for Electric Light Failure.*—One of the customers of the Corporation Electricity Department has claimed £1 10s. damages for the loss of the custom of two persons who were in her shop at the time the electricity supply failed recently, and who refused to wait until the power was renewed.

MIDDLESEX: *Tramway Expenditure.*—The County Council's annual report states that the capital expenditure upon tramway account is £1,607,548, and that a further sum of £495,925 is required to complete the Council's scheme.

OXFORD: *Tramways.*—The Corporation has deposited a petition against the Bill of the National Electric Construction Co., in which it proposed to override the agreement to instal the Dolter surface-contact system, or, in the event of the Corporation not being satisfied with this, any system other than the overhead. The Company now ask, for financial reasons, to instal the overhead system.

SALFORD: *The Electricity Committee.*—The question of the recent resignation of the Chairman and several members of the Electricity Committee came up at the last meeting of the Corporation, but no decision was arrived at. The matter has been referred to the Selection Committee, and a discussion was stopped owing to the question not being on the minutes.

SOUTH SHIELDS: *Advertising on Tramway Posts.*—The Tramways Committee have received an application from a London firm asking for permission to erect illuminated advertising signs upon the tramway standards. The applicants state that the illuminating power of the advertisements will be sufficient to light the thoroughfares. The Committee has decided to interview the Company.

WALSALL: *Electricity Works Accounts.*—The accounts of the Municipal Electricity Department for the year ended December 31st, 1908, show total expenses of £9,101 and receipts of £14,164. For the year ended December 31st, 1907, there was a deficit of £89, and after meeting interest, sinking fund charges, &c., for the year 1908, there is a further loss of £856, making an accumulated deficit for the two years of £945. The number of units generated was 2,115,586, and the total sold, 1,511,277. The total maximum demand was 980 kw.

WHITBY: *Transfer of Electricity Undertaking.*—A resolution made by the General Purposes Committee that the Clerk should write to the Board of Trade asking if it would give its approval to the Council leasing or selling their electric light undertaking, has been rejected. It appears that no offer has been made by an outside company, and that the suggestion emanated solely from the General Purposes Committee.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERTILLERY.—Tenders are invited for the erection of a small generating station by the Urban District Council. Particulars from Mr. Maurice E. Webb, 19 Queen Anne's Gate Mansions, London, S.W., and tenders by February 26th.

BRADFORD.—A scheme of extensions to the electricity undertaking, costing about £50,000, has been brought forward and adjourned for a month.

CARDIFF.—Tenders are invited for the supply, delivery, and erection of 300-kw. motor-alternators. Particulars from the Electrical Engineer, Mr. Arthur Ellis, fee 1 guinea returnable, and tenders to the Town Clerk on May 19th.

HULL.—Sanction has been received from the Local Government Board for borrowing £11,000 for electricity extensions.

ITALY.—The Municipality of Francavilla Fontana invite tenders for the electric lighting of the town. A provisional deposit of £240 will be required to qualify any tender, to be increased to £508 by the successful tenderer. The adjudication will take place on the 26th February, and tenders must be addressed to the "Amministrazione Municipale, Francavilla Fontana, Italy."

LONDON: *Stepney.*—An application is to be made to the London County Council for sanction to borrow £7,860 for house services, mains, meters, &c.

ST. HELENS.—The Electricity Committee invite tenders for the supply and erection of condensing plant, &c. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 17th.

SWINDON.—Having considered a report of the Electrical Engineer on the need of additional machinery at the generating station, the Electricity Committee recommend that the following additional plant should be obtained :—One circulation pump with foundations, pipework, and switchgear, £190; one softener pump with foundations and pipework, £100; one superheater with valves, pipework, and brickwork, £195; weighbridge, £100; one superheater, £175; total, £760; also that the following be paid for out of revenue :—One switch panel for existing circulating pump, £20; one megger (testing instrument), £25.

Miscellaneous

ASHTON-UNDER-LYNE.—The Electricity Committee invite tenders for the following :—Water-tube boiler and engine-driven induced draught fan. (See an advertisement this week.)

BEXLEY.—The Local Government Board has sanctioned the borrowing of £400 for tramway purposes.

CHELMSFORD.—Tenders are invited for the maintenance and repair of the fire alarm system for the Corporation. Particulars from the Clerk, and tenders by February 19th.

ECCLES.—The Corporation invite tenders for the purchase of scrap metal, including old lamp heads, &c., belonging to the Electricity Committee. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by the 13th inst.

ITALY.—A company has been formed in Lugano, with a capital of £20,000, for the purpose of constructing an electric tramway from Lugano to Cadro and Dino.

It is announced that with the Government subsidy of 8,500 lire per kilometre, as well as other subsidies, the construction of the electric railway in the Vigezzo valley is fully assured. The initial plans will, however, have to be modified.

KIRKCALDY.—It has been decided to proceed with the construction of the tramway extension to Dysart, subject to terms being arranged with the Dysart Council.

LINCOLN.—The Corporation invite tenders for an electrical water level recording and telephonic system, connecting the waterworks engineer's office with the proposed new pumping station and water power. Particulars from the waterworks engineer and tenders to the Town Clerk by February 22nd.

LONDON: *London County Council.*—It is recommended that an expenditure of £11,000 be incurred upon the erection of the first portion of the Abbey Wood car-shed, which is needed in connection with the working of the tramways from Beresford Square, Woolwich, to Abbey Wood. Accommodation will be afforded for 30 cars.

It has been reported to the Council that it will be necessary during the next financial year to renew the special track work and cross-overs on the Council's tramways at (1) the junction of New Cross Road and Queen's Road; (2) the junction of Old Kent Road and New Kent Road; (3) Clapham Park Road; (4) Clapham Common; (5) the crossings at St. George's Circus. The cost is estimated at £9,100.

Marylebone.—The Council invite tenders for the fitting of electric fittings, reflectors, switches, &c., to about 2,000 existing street lamps. Tenders to the Town Clerk by February 17th.

ROUMANIA.—Tenders for the construction of an electric tramway in Ploesti will be received at the office of the Mayor on the 3rd/16th March. A concession will be given for working the line for fifty years. A provisional guarantee of £1,000 must be deposited.

WALTHAMSTOW.—The Electricity and Tramways Committee invite tenders for stores during the year ending March 31st, 1910. Particulars from the Electricity and Tramway Engineer, and tenders to the Town Clerk by February 26th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

LONDON COUNTY COUNCIL.—Tenders are invited by the London County Council for wiring and fitting the Redman's Road School, Stepney. Particulars from the Engineer to the Council, and tenders by February 17th.

Tenders are also invited for the installation of electric lighting and bells at the Brixton School extension. Particulars from the Engineer to the Council, and tenders by February 16th.

N.—Alterations, 71 High Street, North Finchley (£2,048). Architect, V. Vagnolini, 33 Stirling Road, Clapham Rise, S.W.

Conversion of Police Station, Kingsland Road, Haggerston, into business premises. Architects, Lovegrove and Papworth, 374 Old Street, E.C.

N.W.—Additions to Theatre of Varieties, Euston Road. Architects, Wylson and Long, 16 King William Street, E.C.

S.E.—Erection of King's Hall, St. George's Market, London Road, Southwark, for W. F. Hurndall, 84 Blackfriars Road, S.E.

S.W.—Lighting, &c., of King's Hall, High Street, Tooting. Architects, Emden, Egan & Co., 2 Lancaster Place, W.C.

Digitized by Google

Erection of Sloane Gate Mansions, D'Oyly Street, Chelsea. Architect, W. Hunt, Norfolk Street, Strand.

PROVINCES.

ALTRINCHAM.—Isolation Hospital. Architect, W. Owen, Clarence Street, Manchester.

BACUP.—Post Office, Burnley Road (£10,000). J. W. Else, Borough Surveyor, Bacup.

BARNSTAPLE.—School, 300 places. S. W. F. Brown, Secretary, Barnstaple Education Committee.

BLAYDON-ON-TYNE.—Secondary School. W. Rushworth, Shire Hall, Durham.

BO'NESS (N.B.).—Church. Steel, Masonic Buildings, Bo'ness.

BRADFORD.—Additions, Sanatorium. City Architect, City Hall, Bradford.

CAMBRIDGE.—Extension of Post Office (£2,788). Builders. W. J. Fryer & Co., Bravington Road Works, Harrow Road, W.

CREWE.—Police Station (£2,000). R. Potts, Clerk to Cheshire County Council.

DUBLIN.—The agenda sheet of the North Dublin Union for this week includes the consideration of a report of the committee of the Board which has inquired into the question of the lighting of the Union. The report recommends the lighting of the Union by electricity, and that a loan of £2,000 at 20 years be applied for carrying out the scheme at once.

DURHAM.—Extensions to Hartlepool Henry Smith School (£11,000). R. Simey, Clerk to Durham County Council.

DARLINGTON.—High school for girls. H. Rushworth, Shire Hall, Durham.

DERBY.—Institute for the Deaf and Dumb (£5,000). Architect, A. Eaton, Long Eaton.

EAST COWES.—Tenders will shortly be invited for an electrical installation at the Town Hall.

ESHER.—Tenders are invited for the wiring of the buildings for electric lighting at the sewage disposal works, Lower Green, Esher. Particulars from the Surveyor, and tenders to the Town Clerk by March 31st.

HAMPSHIRE.—Secondary school, Aldershot; girls' school, Basingstoke; girls' school, Winchester (£8,475); school, Eastleigh (£11,169); school, Farnborough South (£9,365). H. Barber, Clerk to Hampshire County Council, Winchester.

HULL.—Block buildings for Territorial Association. Architects. Wellstead & Dosser, Hull.

HUDDERSFIELD.—School, Wiggan Lane. Architects, Garside & Pennington, 2A Wesley Street, Castleford.

MERTHYR TYDVIL.—The Board of Guardians have under consideration the rearrangement of the electrical supply to the Bedwelty and the Pontypool Workhouses, and a consulting engineer is to be engaged to examine and report on the estimate furnishd by the Merthyr Electric Traction Co.

MIDDLESBROUGH.—Secondary school. Architect, A. Forrester, 20 Albert Road, Middlesbrough.

SOUTH SHIELDS.—Sailors' Home (£8,000). Architect, E. Liddle, Newcastle-on-Tyne.

SHROPSHIRE.—County sanatorium. Earl of Powis, President.

ST. ANNE'S-ON-SEA.—Addition, Technical School. Architect, H. Gregson, St. Anne's-on-Sea.

SUNDERLAND.—Children's hospital. Architects, W. & T. R. Milburn, Fawcett Street, Sunderland.

TIPPERARY.—The Board of Guardians is considering a project for lighting the Workhouse with electricity.

WALLSEND.—Two public amusement halls. Architect and builder, J. Mc. Hary, Park Road, Wallsend.

WINCHESTER.—Additional offices for Hampshire County Council, St. James Street (£20,000). H. Barber, Clerk to the County Council, Winchester.

The Institution Students' Dinner.—The fifth annual dinner of the Students' Section will be held at the Holborn Restaurant on Thursday next, February 18th. We understand that the guests are to include, amongst others, the President (Mr. Mordey), Dr. G. Kapp, and Dr. S. P. Thompson. We have further been informed that Mr. Selwyn Driver (humorist) has been secured to assist in the musical programme.

London Electric Power Supply.—Notice is given of the intention to introduce a Bill in Parliament next session, to constitute the London County Council the purchasing authority of the Kensington & Knightsbridge Electric Lighting Co., the Notting Hill Electric Lighting Co., the St. James & Pall Mall Electric Light Co., the Westminster Electric Supply Corporation, and the Central Electric Supply Co. It will be remembered that the legislation last session in connection with the London electric supply companies, did not make provision for the abovementioned companies to be purchased by the County Council, but an undertaking was given that they would not oppose any future proposals bringing them into line with the other companies, who are now purchasable under the London Electric Supply Act of 1908.

TENDERS RECEIVED AND ACCEPTED

CAPE TOWN.—The order for a 550-volt battery and "Entz" booster in connection with electric power supply to the docks has been placed with the Chloride Electrical Storage Co., Ltd.

EAST HAM.—An order has been placed with Mathews & Yates for a new set of fans required for a cooling tower at the generating station at £51, delivered complete.

FAREHAM.—At the meeting of the Fareham Urban District Council on Tuesday, February 2nd, the tenders for the first sections of generating plant for the new electricity works, which have been designed by the consulting engineers, Messrs. May and Hawes, were brought up for consideration. Thirty-nine tenders were submitted for the four sections, and upon the recommendation of the Electric Lighting Committee the Council decided to allot the contracts as under subject:—Sections A and B: Sulzer Diesel engines and Crompton flywheel alternators, the Diesel Engine Co., Ltd., £5.176 16s. Section C:—High and low pressure switchboards: the Electric & Ordnance Accessories Co., Ltd., £397 9s. 6d. Section D:—Overhead travelling crane: John Smith (Keighley), Ltd., £64.

WIMBLEDON.—An order has been placed with the British Thomson-Houston Co., Ltd., for the supply and fixing of two bottom bucket wheels and diaphragm nozzles for the Curtis turbo-generator at the electricity works, at a cost of £120.

COMPANIES' MEETINGS AND REPORTS

CENTRAL LONDON RAILWAY CO.—At the meeting on Thursday, the report and accounts given in our last issue were adopted. Sir Henry Oakley, who was in the chair, said that the ventilation having been from time to time complained of, they had established a large fan at Shepherd's Bush, which cleared the tunnel every night; but they also found it necessary to provide for ventilation in the daytime. They had, therefore, established a fan at the Museum Station, which drew the foul air from between two of the stations and ejected it into the open air, with very great advantage. They contemplated, after a little further experience of the effect of that arrangement at that place, to adopt it at one or two other places, so as to make the air in the tunnels as perfect as possible. They have had also to spend some money in replacing their wooden platforms with stone or concrete. Taking all things into account, they would have a credit balance of £103,000 on their capital account, and therefore there was no occasion for any financial disturbance in connection with their capital or expenditure. With regard to the revenue account for the past half-year, they had increased their gross receipts by £50.000, and their gross expenses to earn that amounted by £5,234, which he thought was remarkable. The receipts per passenger were practically the same, viz., 2.1/8d. in both half-years. At the same time, they must not take too much credit to themselves for this result, because it was really due to influx of traffic caused by the Franco-British Exhibition at Shepherd's Bush. The Chairman then made some reference to the competition from motor-omnibuses, and stated that the directors had the question of fares under very serious consideration. With regard to the company's Bill which had been deposited in Parliament for extending the line to Liverpool Street, Sir Henry Oakley said that this was part of the original scheme of the company, although the advantages of through booking and inter-communication were not then so well understood. The matter had also been further delayed by the inquiry before the Royal Commission on London Traffic. Now, however, the directors of both the Great Eastern Railway Co. and the Central London Railway Co. were convinced of the need for providing a direct connection at Liverpool Street, whilst the North London Co. had agreed to find the necessary land for the station, provided access was given between the present Broad Street station and the new tube station.

DUBLIN UNITED TRAMWAYS CO.—At the half-yearly meeting on Wednesday last week, the report and accounts, given in our last issue, were adopted. The chairman, Mr. W. M. Murphy, in the course of his speech, called attention to the growth of the goods and parcels service, which promised to yield a permanent addition of £1,000 per annum to their receipts. A new source of income was minerals, the inauguration of which was due to the enterprise of a Lucan gentleman, who, finding a supply of sand upon his property at Howth, opened up a trade for its disposal in the city. He thought this class of trade could be enormously increased if the Harbour authorities would give facilities for getting alongside the ships, but they seemed averse to this. Dealing with the expenditure, he said that the cost of generation, viz., £9,053, was a good deal in excess of any previous half-year, except the corresponding half-year of 1907, when the cars ran 300,000 miles more than in 1908. This was due to the increased consumption of electric current per car-mile. Their electrical engineer, Mr. Sheardown, had for some time been investigating this, and he had been able to eliminate from his calculations as a probable cause of loss in electric current any deterioration in the efficiency of the electric installation. The result of tests showed that where cars were running under conditions, similar as to weight, speed, stops, &c., as when they were first started some years

Digitized by Google

ago, there is little or no change in the power required to drive them, but where heavier cars had been introduced, driven at higher speeds, and stopping frequently, the consumption was in many cases double the old rate. This tendency to increased electric current consumption could be in some measure checked by attaching wattmeters to all the cars, so that the drivers and inspectors could see how their cars were working, and provision was being made for this to be done. Continuing, Mr. Murphy said that it was the intention to start an express service to Dalkey for business people night and morning. It was also mentioned that one of the steel chimneys at the Ringsend power station had been lined with ferro-concrete, in order to improve their durability, at a cost of £1,200, and another was to be put in hand.

ANGLO-AMERICAN TELEGRAPH CO.—The total receipts from July 1st to December 31st, 1908, including the balance of £6,962 brought forward from the last account, amounted to £209,602. The traffic receipts show a decrease of £5,423 as compared with the half-year ended December 31st, 1907. The working expenses amounted to £79,037, being an increase of £5,560, as compared with the corresponding period of 1907. The directors, under the powers conferred upon them by the Articles of Association, have, before declaring the net profits, set apart the sum of £10,000 to the renewal fund, leaving a balance of £120,565. Quarterly interim dividends of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, were paid on November 2nd last, leaving a balance of £68,065, out of which the directors recommend the proprietors to declare final dividends of 19s. per cent. on the ordinary stock, £1 10s. per cent. on the preferred stock, and 8s. per cent. on the deferred stock, payable on February 6th, amounting together to £66,500, making a total distribution for the year ended December 31st, 1908, of £3 4s. per cent. on the ordinary stock, £6 per cent. on the preferred stock, and 8s. per cent. on the deferred stock. The balance of £1,565 will be carried forward. The meeting is to-morrow (Friday).

At the meeting on Friday, the report and accounts were adopted. Mr. H. Benson presided, and in reference to the recent agitation for "penny a word" cables, said that they had received an assurance from the Postmaster-General that the North Atlantic companies would have the opportunity of expressing their views at the forthcoming conference before any definite proposals were adopted.

GREAT NORTHERN & CITY RAILWAY CO.—At the half-yearly meeting on Friday, the report and accounts given in our last issue were adopted. The Earl of Lauderdale, who presided, said that £17,013 was carried to net revenue account as against £22,804 last year. The working expenses showed a reduction of £2,965. The alterations made in the fares in November, 1907, when the electric trams began to affect the company, had really mitigated the company's losses. It was at present out of the question to attempt the extension to the Bank for which they held Parliamentary powers, as they could not place their unissued capital as prior securities to enable them to do this. If it were possible to do so, they might get beyond the sphere of tramway interference, and by landing their passengers at the Bank induce a large number of them to return to the use of the line. Were it not for the low fares on the London County Council trams the company would be able to compete much more successfully than at present. Their fares for the time being were more or less governed by the terms of their agreement with the Great Northern Railway, but they had taken steps which would give them more freedom of action in the matter. They had hardly been assisted in the matter by the Great Northern Co., several of whose trains now ceased calling at Finsbury Park Station, and thus deprived them of a considerable number of interchange passengers. The acceleration of the Great Northern Railway Co.'s service to King's Cross had also militated against the tube company's interest. At the present moment they were working at a loss, but there was a minimum below which they could not reduce their expenses. They had their fixed charges to consider. They had failed to meet them this half-year, and it was doubtful whether they would be able to do so in the current twelve months. The situation was, therefore, acute, and it might be necessary to deal with it in a drastic manner.

TYNESIDE TRAMWAYS & TRAMROADS CO.—The accounts for the half-year ending December 31st, 1908, show that the surplus of receipts over expenses is £3,203, which, with the balance brought forward from last half-year of £728, makes a balance of £3,931, and after deducting interest on debentures, loans, &c., there remains an available balance of £2,792. The directors propose a dividend on the preference shares of 5 per cent. per annum (less income tax); a dividend on the ordinary shares of 1½ per cent. per annum (less income tax) as compared with 2½ per cent. for the corresponding half-year of 1907; and to place £600 to the credit of reserve for renewals, depreciation, and other contingencies, thus increasing the amount to £6,100, leaving to be carried forward to next half-year £642. The decreased profit for the half-year as compared with the corresponding period of last year is entirely consequent upon the reduction in receipts amounting to £886, against which the reduction in running expenses is only £304. This falling off of revenue is attributable to the smaller traffic on the company's lines caused by labour troubles and depression in trade, which have been prevalent in the district during the greater part of the period. At the meeting on Tuesday, the report and accounts were adopted.

BRITISH ALUMINIUM CORPORATION.—An extraordinary general meeting was held in London last week, when a resolution was passed dividing each of the £10 1908 conversion shares into two shares of £5 each, one being a 7 per cent. preference share, and the other an ordinary share. Mr. J. D. Bonner, who presided, said that the Lochleven works were now capable of production, and that as the pool had been broken up, aluminium was selling at about £60 per ton.

LONDON ELECTRIC SUPPLY CORPORATION.—At the ordinary general meeting on Tuesday, the report and accounts given in our last issue were adopted. Mr. R. H. Benson, in his speech, detailed the question of power supply in London in relation to the Parliamentary proceedings last session, and impressed upon the shareholders that they had gained the undisturbed possession of their field until 1931, when they were then liable to be bought up by the London County Council, and also the economy from the working with instead of against other companies or municipal authorities. With regard to the contract with the London, Brighton and South Coast Railway Co., he said the minimum number of units per annum for this service was to be 4,000,000, but, if necessary, they could supply the railway company with 40,000,000 units. Since 1903 their lighting business had increased by 38 per cent., and the power business, other than that supplied to the London County Council, by 1,274 per cent. The works costs per unit sold had gone down from about 2¼d. per unit to 0·63d. per unit, and the total costs, including distribution, from about 3d. to 1·09d. Summing up, he said their position to-day was sounder and more promising than they had ever known it.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—The accounts for the half-year ending December 31st, 1908, state that the traffic of the company shows a steady, progressive, and most satisfactory increase, occurring at every station on the railway, and being most marked in the through traffic exchanged with other railways. The gross receipts amounted to £94,066, being an increase of £19,738, or 26·55 per cent. on the receipts for the corresponding half of 1907. The working expenses amounted to £57,242, being a decrease of £4,111, or 6·70 per cent. The net revenue of £37,941 is sufficient to provide for interest on the total amount authorised to be raised by debenture stock, and after payment of all interest and other charges there remains a credit balance of £6,101, which the directors recommend should be carried forward to next half-year's account. The number of passengers carried was 13,015,363, compared with 9,881,357 in the corresponding period of 1907; the average receipt per passenger was 1·65d., compared with 1·71d.; and the train mileage was 818,059, compared with 883,036. The meeting is on the 18th inst.

X-Ray Dermatitis.—We regret to hear that Mr. H. W. Cox, the manufacturer of X-ray apparatus, of Gray's Inn Road, has had to undergo an operation for X-ray dermatitis as a consequence of which he has lost three fingers of his right hand. One of the fingers of his left hand was amputated for the same reason a few years ago. The King has sent a message of sympathy to Mrs. Cox.

Telegraph Traffic.—The landlines between Constantinople and Konia, and Constantinople and Yozgat, were not working on the 2nd inst., but repairs were effected on the 6th inst. The cable between Falmouth and Bilbao belonging to the Direct Spanish Telegraph Co., which was interrupted on January 19th last, was again in working order on the 3rd inst. It is curious that, notwithstanding President Castro's departure from Venezuela and the political events which subsequently took place, no notice has yet been issued of restoration of normal telegraph communication with Venezuela. On the 6th inst. the cable between Kotaradja and Sabang was again working. Telegrams for the provinces of Messina and Reggio Calabria are now admitted under normal conditions.

Accident on the Lancashire & Yorkshire Railway.—In connection with the recent accident on the electric line between Liverpool and Southport, several travellers on the line are agitating for modifications in the construction of the carriages used on this line. According to *The Yorkshire Post*, the Board of Trade has been approached and has replied that it has no statutory powers in this matter, and that the responsibility for the safety of the passengers rests with the railway company. The Board, however, brings to the notice of the company any specific complaints relating to overcrowding or other matters which it receives. At a meeting of the Birkdale District Council, a resolution was passed requesting the Board of Trade to make regulations with regard to the construction of carriages, the number of exits, &c.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net, c.i.f. port of arrival, quoted on Tuesday night, was £61 10s. to £62 per ton.

DISSOLUTION OF PARTNERSHIP.—The partnership between A. Bowker and Wm. Scholes, carrying on business as Electrical and Mechanical Engineers at 4 Corporation Street, Manchester, has been dissolved.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Notice is given of an intended dividend in the winding up of the Empire Electric Light & Power Co., Ltd. The liquidator is W. Allnutt, 5 Lime Street, London, E.C., and the latest date for receiving proofs is February 20th.

R. Russell, trading as R. Russell & Co., electrical engineers, the Garage, Dryad Street, Felsham Road, Putney, has been adjudicated bankrupt.

A public examination of Mr. J. Bojesen was held on Thursday last at the Court of Bankruptcy before Mr. Registrar Giffard. The liabilities were returned at £7,388, of which £4,912 were expected to rank with assets of £1,586. In July, 1905, the debtor promoted the De Forest Wireless Telegraph Syndicate, Ltd., with a capital of £120,000, to which he sold certain wireless telegraph patents for £5,000, and £100,000 in fully-paid shares. The company went into liquidation in September, 1906. Previously, however, the Amalgamated Radio-Telegraph Co. had been formed, but this went into voluntary liquidation a few months back. The examination was concluded.

Notice of an intended dividend is given in the bankruptcy of W. T. Garnett, trading as W. T. Garnett's Cable Co., Barkerend Mills, Bradford. The last day for receiving proofs is February 25th. The trustee is Mr. Edgar Musgrave, 1 Bank Street, Bradford.

MISCELLANEOUS CITY NOTES

MATHER & PLATT.—A dividend of 10 per cent. is recommended on the ordinary shares for 1908, with a bonus of 7½ per cent.

BUENOS AYRES: GRAND NATIONAL TRAMWAYS CO.—A general meeting has been convened to ratify a provisional agreement for the sale of this company to the Anglo-Argentine Tramways Co., Ltd.

CITY OF LONDON ELECTRIC LIGHTING CO.—The directors have resolved, subject to the completion of the audit, to place the sum of £45,500 to reserve, and to recommend the following dividends:—6s. per share for the half-year ended December 31st, 1908, on the preference shares, making, with the interim dividend paid in July, 1908, a total distribution of 12s. per share, or at the full rate of 6 per cent. per annum; 7s. per share on the ordinary shares, making, with the interim dividend of 5s. per share paid in July, 1908, a total distribution of 12s. per share for the year ended December 31st, 1908, being at the rate of 6 per cent. per annum; and to carry forward a balance of about £26,500.

TELEGRAPH CONSTRUCTION & MAINTENANCE CO.—A dividend of 10 per cent., in addition to the 5 per cent. already paid, making 15 per cent. for the year 1908, is recommended.

APPOINTMENTS AND PERSONAL NOTES

Mr. W. T. Kerr, the Electrical Engineer to the Hereford Council, having received an offer of a post in India at a salary of £400, rising to £600 per annum, the Corporation have, upon the recommendation of the Electricity Committee, decided to increase Mr. Kerr's salary from £200 to £300 per annum, upon which understanding he will remain at Hereford.

Mr. Traynor has accepted the chairmanship of the Bray Electric Lighting Committee.

Mr. D. M. Kinghorn has resigned his appointment as Electrical Engineer to the Southwark Borough Council. The resignation is the result of a difference between the Engineer and the Council with regard to coal contracts.

The Gillingham Council will shortly advertise for a switchboard attendant.

Mr. F. A. Wilkinson, the Electrical Engineer and Manager at St. Marylebone, has resigned his appointment in order to take up private practice. He has entered into an arrangement under which he remains at Marylebone until the end of September, or for six months after his successor takes up his full duties, whichever is the later date. He is now at liberty to carry out such private work as will not unreasonably interfere with his duties at Marylebone. Mr. Wilkinson intends to devote his attention particularly to colliery work, electric battery traction, and electric heating and cooking, &c., following up the work that has been carried out in this direction at Marylebone.

NEW PUBLICATIONS

"Heavy Electrical Engineering." By H. M. Hobart. (London: Archibald Constable & Co.) Price 16s.

"Science Abstracts." January. Section A: Physics; Section B: Electrical Engineering. (London: E. & F. N. Spon, Ltd.) 1s. 6d. each.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **9d.** per line (column width)

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of 1/- for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 205-6, Temple Chambers, London, E.C.

COUNTY BOROUGH OF SALFORD.

ELECTRICITY DEPARTMENT.

THE ELECTRICITY COMMITTEE OF THE SALFORD CORPORATION invite Tenders for carrying out the following work at the Corporation Electricity works, Frederick Road, Pendleton.

SPECIFICATION V. 26.—*Sinking a Bore Hole and Supply of Pumping Plant.*

Specification and Form of Tender may be obtained on application at the Office of Mr. Victor A. H. M'Cowen, M.I.E.E., the Borough Electrical Engineer, Frederick Road, Pendleton, on payment of a deposit of 2 Guineas, which will be returned provided a *bona fide* Tender has been sent in and not withdrawn.

Extra copies may be obtained at 10s. each, which is not returnable.

Sealed Tenders, endorsed "Tender for Sinking a Bore Hole, etc," addressed to the Chairman of the Electricity Committee, must be delivered at the aforesaid Offices of the Borough Electrical Engineer on or before Noon on Monday, the 1st March, 1909.

The Committee do not bind themselves to accept the lowest or any Tender.

(Signed) L. C. EVANS,
Town Clerk.

Town Hall, Salford.
8th February, 1909.

BOROUGH OF ASHTON-UNDER-LYNE.

ELECTRICITY DEPARTMENT.

THE ELECTRICITY COMMITTEE invite Tenders for the following works, viz:—

Section A.—For one Water-tube Boiler.
" B.—For one Engine-driven Induced Draught Fan.

Copies of the Specifications and Form of Tender can be obtained from the Borough Electrical Engineer, Wellington Road, Ashton-under-Lyne, on payment of a deposit of One Guinea, which will be returned on receipt of a *bona fide* Tender.

Sealed Tenders, endorsed "Electricity Works" addressed to the undersigned, must be received not later than 12 noon on Wednesday, March 3rd, 1909.

By order,
JOHN NEAL,
Borough Comptroller.

Town Hall,
Ashton-under-Lyne.
February 9th, 1909.

TRAVELLERS WANTED with connections in the United Kingdom amongst consumers and dealers in Oils, Varnishes, Colours, and kindred goods. Anyone possessing the above qualifications can make a very remunerative income. Preference given to those taking same as a side line.—Address, "Z. 1327," c/o DEACONS, Leadenhall Street, London, E.C.

WANTED, an Engineer having a practical acquaintance with modern electrical developments. Such engineers are in demand, and command large salaries. You can quality at home, under experts, and by a unique system. Prospectus free, THE BRITISH CORRESPONDENCE SCHOOL OF ELECTRICAL ENGINEERING, Dept. M., 36, Maiden Lane, Strand, London.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A letter from the Union Electric Co., Ltd., finds fault with us for referring to the Bremer and Högner patents as the two fundamental patents under which the "Excello" lamp is manufactured. (Page 153.)

In a Paper read last week in London, Mr. H. B. Poynder dealt with the electric driving of factories and workshops. After giving some notes on the rating of three-phase motors, the author pointed out the various difficulties that were met with in the electric driving of different kinds of machinery, and showed how these difficulties had been overcome. In the case of printing and paper-making machinery, he advocated the use of the Ward-Leonard system in preference to direct drive by three-phase motors, and explained a system suitable for the driving of calico-printing machines, in which the power was distributed to the motors by means of a five-wire D.C. system, the motor armatures being supplied at nine different pressures in order to obtain the varying speeds necessary. (Page 154.)

We describe the mechanism of two flame arc lamps. One of these has only recently been put upon the market, and has vertical carbons. (Page 155.)

In a lecture before the Royal Society of Arts on Monday last, Mr. Leon Gaster reviewed the recent developments in electric lighting. The lecturer emphasised the importance of efficient artificial illumination as a means of preserving the eyesight, and referred to the possible dangers from ultra-violet rays. The need of co-operation between the lamp manufacturers and central station authorities for the purpose of protecting the consumer from vendors of inferior over-run lamps was insisted upon. Some interesting novelties in lamps were exhibited. (Page 156.)

A new pattern of ampere-hour meter of the type in which a copper cup immersed in mercury rotates in the field of a permanent magnet has been put upon the market by the British Thomson-Houston Co. (Page 157.)

A Paper was read last week by Mr. Clatworthy describing the electrically-driven and automatically-controlled hydraulic pumps at the new Bristol Docks. These are driven by shunt-wound motors, and the

Digitized by Google

motor-operating, starting, and speed-regulating switches are controlled through relays by tappet switches on the hydraulic accumulator, so that the pumps are started up in a certain order, which can be varied by change-over control switches. The pumps start against full load, as no bye-pass or relief valve is provided. (Page 157.)

A CONFERENCE of Scotch municipal authorities was held on February 3rd to consider the proposals of the North British Electric Power Syndicate to supply electrical energy without statutory powers to consumers alongside the Scotch railways, using the railway tracks for the purpose of laying mains. Agreements on this latter point are said to have been come to with the North British Railway Co. and the Caledonian Railway Co. A resolution was passed calling upon the Board of Trade to pass legislation prohibiting the supply of electrical energy except under statutory powers. (Page 159.)

MR. P. F. ROWELL has been appointed Secretary of the Institution of Electrical Engineers in succession to Mr. Lloyd, who has been appointed Secretary to the Iron and Steel Institute. Mr. Rowell has hitherto been Assistant Secretary of the Institution of Electrical Engineers. An advertisement invites applications for the post of "Accountant-Clerk" for the secretarial staff of the Institution. (Pages 159 and 168.)

IN a Paper read informally before the members of the Newcastle Local Section of the Institution of Electrical Engineers, Mr. C. Turnbull attempted to classify the various processes in the evolution of inventions. (Page 159.)

MR. A. H. WALTON has been elected to the Council of the Institution of Electrical Engineers in place of Prof. Schwartz, who recently resigned. (Page 161.)

MR. ARTHUR WRIGHT has reported to the Brighton Corporation the need of increasing the boiler plant at Southwick at once.—The proposal to introduce the trackless trolley system at Dundee has again been referred back to the Tramways Sub-Committee.—In announcing an inquiry into a scheme of street-lighting at Finchley, the Local Government Board has asked to what extent the cost of public lighting by electricity has been considered.—The National Electric Construction Co. has sent a long letter to the Hythe Council, in which they say that the overhead system is the only one commercially practicable.—An Electrical Contractors' Association has been formed at Montreal.—The municipal authorities concerned with the proposed tunnel under the Tyne refuse to be responsible for the debenture interest until the railway is working.—The Swansea Corporation propose to assess the National Telephone Co.'s undertaking there upon the aggregate earnings instead of at the rate of £1 per mile of wire. (Page 163.)

A 500-kw. generator driven by an exhaust-steam turbine is to be installed at Darlington. Gas-engine generating plant is required at Abertillery; a balancing set and feeder cables at Brighouse; 1,500-kw. rotary converters, 575-kw. static transformers, and high- and low-tension switchgear by the London County Council; and a 350-kw. generating set by the Lowestoft Corporation. (Page 164.)

A PAPER read by Messrs. Leonard Andrews and Reginald Porter, before the Institution of Electrical Engineers last Thursday, started a discussion on steam turbines *v.* gas engines for electric power-houses. The authors of the Paper have estimated the costs for a large generating station alternatively with steam and gas plant, and have arrived at the conclusion that with the price of coal above a certain figure, and with a sufficiently high load factor, gas plant is more economical either than steam plant or than a combination of steam and gas engines. The figures are worked out in considerable detail. In the discussion in London, Mr. W. B. Woodhouse, of the Yorkshire Power Co., and Mr. E. J. Fox, of Willans & Robinson, championed the cause of the steam turbine, giving reasons for disputing the applicability of the authors' estimates without considerable modification. Mr. Fox particularly laid stress on the flexibility of turbine plant for meeting the peculiar demands of an electricity supply load. Mr. R. A. Chattock, Chief Electrical Engineer to the Birmingham Corporation, who is at present engaged in weighing the advantages of gas and steam plant for a big extension scheme, also reviewed the figures and statements in the Paper in some detail; and Mr. Percy R. Allen, of the Castner Kellner Alkali Co., gave an account of his favourable experience with gas plant in a large generating station. (Page 169.)

AMONG the specifications published by the Patent Office on Thursday last was one by A. M. Taylor relating to the use of storage-battery sub-stations on alternating-current systems. A flame arc lamp with converging carbons which are fed down alternately instead of simultaneously, is described in a specification by H. E. Moul; and J. Howard has patented the provision of auxiliary leading-in wires in metal filament lamps for use in the process of exhaustion. A specification by A. R. Low relates to the ventilation of laminated iron cores, and another by Körting & Mathiesen Akt.-Ges. describes a method of preventing the deposit of ash on the globes of flame arc lamps. F. Lüling has patented an automatic rocking switch for controlling three or more groups of lamps on an advertising device. Short abstracts of the above specifications are given in our Patent Record, together with classified lists of the specifications published to-day, and the more important of the patents which have become void through non-payment of renewal fees. (Page 174.)

SOME critics might accuse Messrs. Andrews & Porter, the authors of the Paper advocating gas-driven electricity works read before the Institution of Electrical Engineers last Thursday, of devoting the greater part of their Paper to a problem of academical rather than practical interest. The question which the Paper sets out to solve primarily is whether gas or steam plant will be the more economical for a station having a load of 8,000 kw. at a load factor of 24 per cent., and there can only be comparatively few cases in this country in which an entirely new station of this magnitude is in contemplation. In considering the problem, however, the authors have gone into great detail, and have treated the subject in such a way as to invite a general discussion on the merits of steam and gas plants; so that even if, in the latter part of the Paper, they had not extended their investigations to smaller stations, an interesting and instructive debate would have been assured. Partly owing to the interest now taken in gas engines as a possible important factor which may eventually modify central station design, and partly owing to the "sporting" instinct which led members to anticipate an energetic discussion, the meeting was crowded. The authors' case was put with extreme clearness, and the discussion—which will be continued next week—was practical and to the point. Three faults were found with gas-engine stations. First, they are necessarily "small unit" stations, as the limited overload capacity of the gas engine makes it advisable to use a greater number of sets than in the equivalent steam-driven station in order to have sufficient reserve. Secondly, the authors' assertion that the cost of repairs and maintenance would be no more than in a steam station was challenged; and, thirdly, the greater

Digitized by Google

flexibility of the steam turbine to meet the peculiar conditions of load in an electricity supply works was insisted upon. This last point, brought forward by Mr. E. J. Fox, is important, as it is one that is apt to be overlooked in predetermining results on paper. The high efficiency of the steam turbine at half and three-quarter load, and not only its overload capacity but its overload efficiency, mean considerable savings in the coal bill. From the instances quoted by Mr. Fox, it would look as if the authors' "discrepancy factor" will be far less in turbine stations than in others. The same speaker's record of 6d. per kw. per year for the maintenance of turbines and condensers will be reassuring to those who have too vivid a recollection of the troubles experienced with some of the earlier makes of machines, and it would be interesting to know by what percentage it might be increased to include the generators. It is too much to hope, however, that the fight between steam and gas plant will resolve itself into a battle of maintenance guarantees.

An interesting sequel to the recent application of the West Ham Corporation for a loan for electrical extensions, and the refusal of the Local Government Board to continue the inquiry in the absence of specific figures relating to certain power contracts, was heard in the Law Courts on Tuesday before Mr. Justice Neville. Owing to the deadlock between the Corporation and the Local Government Board, and the fact that power developments are going ahead in West Ham very rapidly, it has been necessary for the Corporation to obtain considerable overdrafts from their bankers, and as the interest upon this has to come out of the rates, an application was made to restrain the Corporation from enforcing the payment of these rates, pending an action challenging the legality of obtaining such overdrafts in the absence of consent from the Local Government Board. The present position, we believe, with regard to the Local Government Board inquiry is that the Corporation called in Mr. Arthur Wright to go into the contracts in question, which, it was alleged, had been made at prices below cost, to advise them as to their fairness or otherwise, at the same time maintaining their refusal to divulge the prices. As a consequence, the estimates placed before the Local Government Board in the first instance were revised, and an application was made for the inquiry to be resumed, but so far this has not been done.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 18th.

Institution of Electrical Engineers: Students' Section.

7 for 7.30 p.m. Annual dinner at the Holborn Restaurant, London.

FRIDAY, FEBRUARY 19th.

Institution of Electrical Engineers: Leeds Section.

6.30 p.m. Annual dinner at the Metropole Hotel.

Institution of Civil Engineers.

8 p.m. Special Lecture by Dr. W. C. Unwin, F.R.S., on "Standardisation in Engineering Practice."

SATURDAY, FEBRUARY 20th.

Electrical Football League.

3.15 p.m. The following matches will be played to-day: St. Pancras Electric *v.* St. James Electric at Swain's Lane, Highgate; Robertson Lamps *v.* Metropolitan Electric at Gunnersbury Avenue, Ealing.

Central Technical College Old Students' Association.

7.15 for 7.30 p.m. Annual dinner at the Trocadero, Piccadilly.

MONDAY, FEBRUARY 22nd.

Royal Society of Arts.

8 p.m. Cantor Lecture II.: "Modern Methods of Illumination," by L. Gaster.

TUESDAY, FEBRUARY 23rd.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Meeting at the University. Paper to be read: "Load Equalisers," by J. S. Peck.

Faraday House Old Students' Association.

7 for 7.30 p.m. Annual dinner at the Queen's Hotel, Leicester Square.

WEDNESDAY, FEBRUARY 24th.

Electrical Football League.

7 p.m. Council meeting at 19 Carnaby Street, W.

THURSDAY, FEBRUARY 25th.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, when Messrs. Andrews & Porter's Paper on "The Use of Large Gas Engines for Generating Power" will be resumed.

CORRESPONDENCE

FLAME ARC LAMP PATENTS.

To the Editor of Electrical Engineering.

Sir.—We notice in your editorial of February 11th that you allude to the Högner patent, owned by Messrs. Körting & Mathiesen, as "the other" fundamental patent under which the "Excello" lamp is manufactured by them and sold in this country by us. We would point out that the "Excello" arc lamps, both for direct and alternating current, are manufactured under several patents, and that the patent to which you refer is in no sense *the* fundamental patent of the "Excello" lamp to the exclusion of others. The phrase in your editorial might lead to the conclusion that, should the decision of the Comptroller be to revoke the Högner patent, the "Excello" arc lamp was not protected by patents—a conclusion which would be quite erroneous.

Yours faithfully,

J. Eck,
Secretary.

Park Street, Southwark, London, S.E.,
February 16th, 1909.

ELECTRIC POWER AND SUCTION PLANTS.

To the Editor of Electrical Engineering.

Sir,—Referring to the recent correspondence in your pages on the above subject, your correspondents on both sides appear to neglect the fact that the advantages obtained by electric power are almost entirely indirect.

It is very rarely that, taking average prices, the cost of power, with everything taken into consideration, in the case of electric driving is less than with suction gas, but the increased cost can often be compensated for by other advantages obtained—notably, increase of output, convenience, and saving of space, which latter is usually valuable, and can be more profitably employed by money-earning plant. Secondly, in comparing electric power with gas or steam plants, the fact that a steam or gas engine is a prime mover, whereas the electric motor is a secondary engine, is scarcely ever taken into consideration. The function of the steam or gas engine is power production and of the electric motor-power transmission.

Unless the foregoing facts are carefully borne in mind, comparisons are valueless.

Yours faithfully,
For Walters & Co.,
Vincent E. Walters.

Ocean Chambers, Waterloo Street,
Birmingham, *February 12th*, 1909.

New Technical Journal.—The publication of a new weekly journal devoted to the iron and steel industry, with the title of *The Iron and Steel Times*, is announced. The founder of the new enterprise is Mr. Strahan Smith, late of the *Times* Engineering Supplement.

ELECTRIC DRIVING OF FACTORIES AND WORKSHOPS

IN a Paper read before the Association of Engineers in Charge on February 10th, Mr. H. B. Poynder, of Messrs. Siemens Bros.' Dynamo Works, Ltd., dealt with the electric driving of machinery in factories, workshops, collieries, and mills. After describing the different types of three-phase motors, the author deals with the rating of such motors as follows :—Manufacturers, he says, are often asked for motors of such and such an output, and, on investigation, it is found that the horse-power asked for is based on the maximum torque required to start the driven machine, the customer having overlooked the fact that a motor is quite capable of giving a very considerable temporary overload. Where a large starting torque is required the manufacturers should be asked for a motor to give the normal power, and the starting torque should also be specified, with the approximate length of time it is likely to last.

Some engineers are inclined to allow a considerable margin over the estimated horse-power required when ordering motors. This can be overdone, since the effect of a moderate overload is merely to increase the heating which well-made motors will stand without damage. If the motor is much too large for its work, the disadvantages are : increased capital outlay, reduced efficiency, and a reduction in the power factor.

An important point is the effect of voltage drop on the torque which falls off proportionally to the square of the voltage. If the station voltage is variable, or if the cables are of insufficient size, it is as well to allow a margin and to instal a motor capable of giving, say, 15 per cent. or 20 per cent. more torque than is ever likely to be required. If such a fall of volts is likely to occur regularly, whenever a load comes on the motor, then the motor should be ordered for the reduced voltage, as it will do it no harm to run light at a rather higher voltage than that for which it is designed.

For engineering workshops, the author continues, a mixed system of individual and group driving should be adopted. A shop full of automatic lathes turning out small standard parts has usually a large number of tools in a comparatively small space, and these should be driven in groups, but for the large tools in a large machine bay, which are probably some distance apart, and which are frequently stopped for long periods, individual drive is the best. Planing-machine makers now realise the enormous power required for reversing the table, and are introducing mechanical devices to get over this trouble. Messrs. Buckton, for instance, use a large spiral spring to retard the table at the end of its travel. This spring gives out the stored energy on the return stroke, thus relieving the motor of the work of accelerating the table. In punching and shearing machines, and many others, however, the peak load is caused by the actual work of the tool, and it is difficult to reduce the peak load. A flywheel cannot give out energy unless its speed is reduced, and, as a normal polyphase motor drops in speed very slightly unless the torque is sufficient to stop it, the addition of the flywheel does not help it, unless special steps are taken to make the motor drop in speed. The ideal method is to use an automatic apparatus, such as is used for rolling-mill motors, to increase the rotor resistance when the peak load comes on, thus allowing it to drop in speed without taking a heavy current. Such an apparatus, however, is quite unsuitable for cases in which the peak loads are frequent, and of short duration, as it must have a certain amount of time lag, and it is also unsuitable in any case for small motors, on account of its cost. Nearly as good results can be obtained in practice by a small permanent resistance, either in the form of high-resistance short-circuiting rings if it is a squirrel-cage motor, or as a permanent step left in the starter in the case of the slip-ring type of motor. This resistance is, of course, always in circuit, but it does not waste much more power than the automatic slip resistance .

In wood-working shops the machines are generally at some distance apart, and individual driving is, therefore, best. For fan, pump, and compressor driving the starting arrangements are most important. The ordinary centrifugal or propeller fan, and the centrifugal pump, take an extremely small torque to start them, and the Star-Delta starting arrangements are suitable even for large sizes. Ram pumps and air compressors require more than full torque at starting unless they are fitted with a by-pass. Air pumps require considerably more than full-load torque at starting.

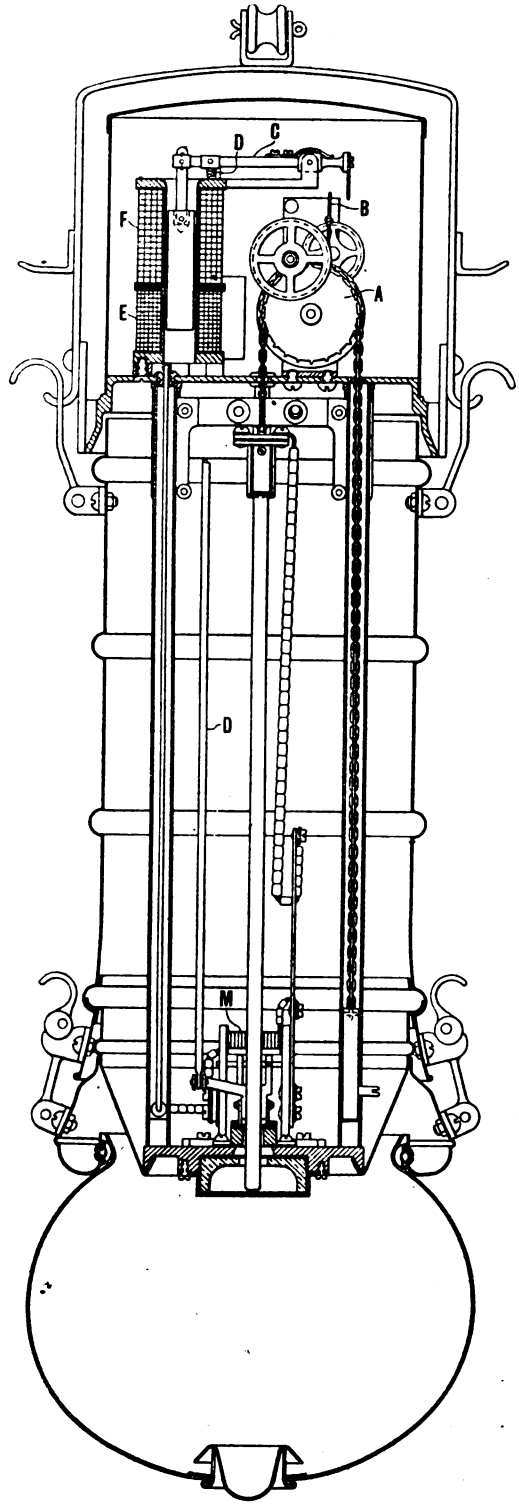
Referring to colliery work, the author describes briefly the Ward-Leonard, Ilgner, and the three-phase systems of winding. In the last-named system some sort of buffer or load-equalising set has to be worked in parallel with the three-phase motors to average up the load. In connection with the driving of rolling mills, the author points out that there are two types of rolls in general use. The one is the two-high, in which the rolls are reversed for each pass, and the other is the three-high, which run continuously in one direction. For the latter, which are generally fitted with a heavy flywheel, a three-phase motor, with automatic slip resistance, is evidently suitable, the resistance being inserted in the rotor circuit, whilst the ingot is passing through the rolls, thus allowing the flywheel to help the motor over the peak load. For the two-high rolls, however, which have to be reversed at every pass, and, therefore, cannot have a flywheel, the Ilgner system must be used. Messrs. Siemens Bros.' Dynamo Works, Ltd., are at the present time supplying a motor and Ilgner set for a large reversing rolls in the north of England: the actual horse-power is 8,000, with an overload capacity up to 12,000 b.h.p. In textile mills it is found that electric driving gives such an even turning movement that, not only can the speed of the machines be increased, but even at this increased speed a finer quality of work is produced. This applies particularly to spinning and weaving. Looms require individually but little power, but in the average weaving-shed a very large waste of power takes place in the shafting. Also a considerable number of looms are always standing whilst knotting broken warp threads and refilling shuttles. It is thus found that, despite the rather low efficiency of small motors, a considerable economy in power is obtained by adopting the individual system of drive. Further, in most cases, the number of picks per minute can be increased some 10 per cent., and even at this higher speed there is a considerable reduction in the number of broken threads, which reduces the standing time, often giving another 10 per cent. increase in output. Again, with the individual drive a very sharp start can be obtained, and the first throw of the shuttle after a stoppage has the full normal velocity, which is not the case with the ordinary belt drive from shafting. The result of this is that there is no mark in the fabric at this point, which is a considerable advantage with delicate materials.

For paper-making and printing machinery a creep is necessary at starting whilst making adjustments, and for the paper machine, widely different speeds are necessary for the different qualities of paper which are often turned out from a single machine, whilst for printing machines a somewhat smaller speed range is also usually required. In these cases, therefore, the Ward-Leonard system is probably the best, although it necessitates a motor generator set to produce the variable voltage direct current. In both cases fine regulation is necessary so as to enable the speed to be gradually increased without jerks.

For calico printing, also, a wide speed regulation is required, but smooth and gradual acceleration between one speed and another is not wanted, and, therefore, seven or eight speeds intermediate between standing and full speed suffice. The best method to adopt in this case, assuming that a three-phase supply is available, is to instal in the power-house a single motor-generator set consisting of an induction motor and three or four direct-current generators, coupled together. The voltages of these generators are suitably graded; they are connected in series, and distribute on to a four- or five-wire network, from which a number of different voltages can be obtained. Each printing machine is driven by a direct-current motor with its field excited at constant voltage, and by means of a special controller the armature can be connected in turn across any two of the wires of the network. The various voltages of the generators previously referred to are so arranged that with the five-wire system nine equally-spaced voltages can be obtained. No resistances are necessary for starting, the armature being successively connected across the increasing voltages, and left across that one which gives the desired speed. Where there are a number of machines, this method shows a great economy in power, as no energy is wasted in the resistances either for starting or regulating, and the capital saving due to the absence of the large rheostats, which would otherwise be required for each printing machine, goes a long way to pay for the special converter set. Where a direct-current supply is available, instead of alternating, a motor to drive the set of generators is not required, as it will run automatically like a balancer across the mains.

A special feature in sugar refineries is the driving of the hydro-extractors. In some cases the motors are built in with the machine, the motor being mounted direct on the vertical spindle. It is doubtful, however, whether this is altogether advisable, as it is hardly possible to use the ordinary small air-gap, since the spindle of the hydro-extractor is likely to be slightly out of truth. If a specially large air-gap between the stator and the rotor is used, the efficiency and power factor of

Digitized by Google



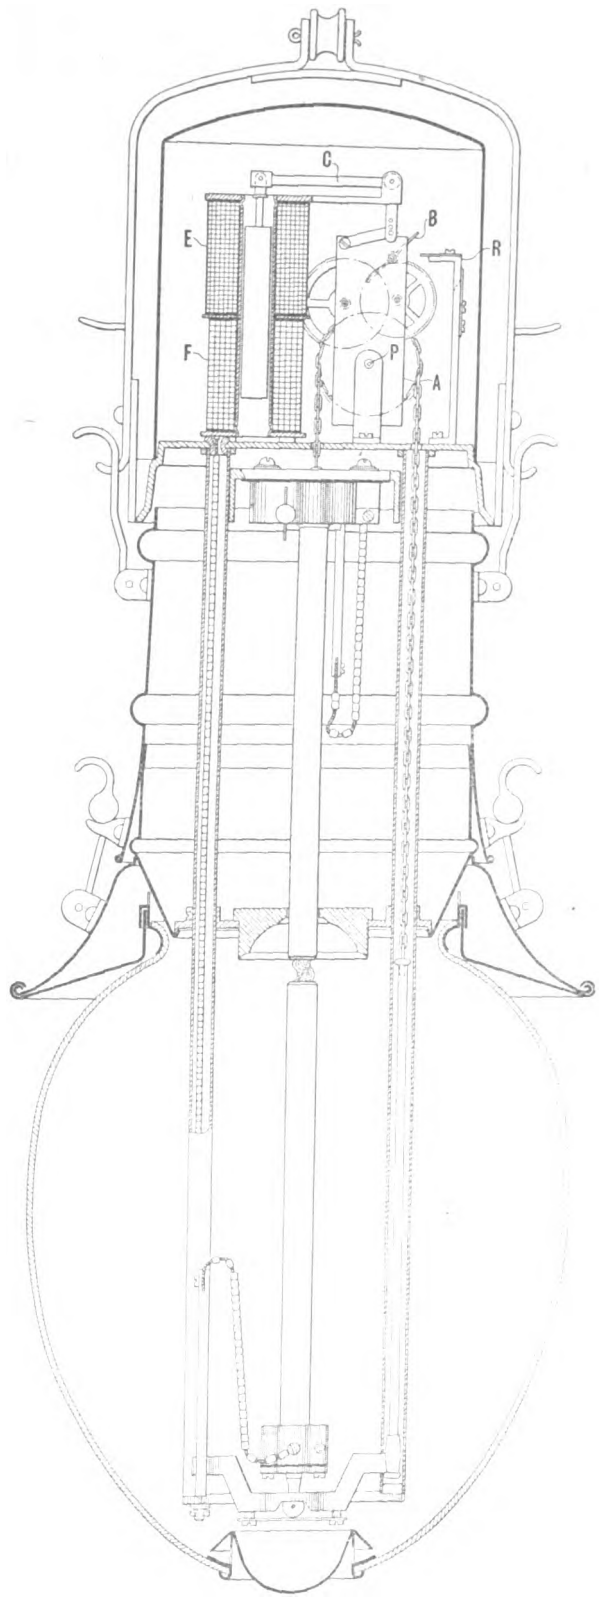
the motor suffer. Where there is room available, an ordinary horizontal motor driving the centrifugal through a ¼ twist-rope or belt-drive should be used. These centrifugals, when charged with sugar, take a very large power to accelerate them up to speed; but at full speed a comparatively small power is required. The most satisfactory arrangement is to have an induction motor with a stator specially wound with, say, four different numbers of poles, the motor having a plain short-circuited rotor. Such motors can be switched straight on to the mains with the lowest speed stator connections, and the other connections are then made successively as the speed rises. Only one-half of the energy is required during the acceleration period, and, when stopping, a considerable portion of this energy is returned to the line, since by switching over to the reduced speed connection regenerative braking is obtained so long as the centrifugal is running above the corresponding speed.

TWO FLAME ARC LAMPS

THE accompanying illustrations are sectional elevations of two flame arc lamps, placed on the market by Messrs. Marples, Leach & Co., Ltd., and known as the "Prima" and "Rebofa" lamps respectively. The first-named is of the usual converging carbon pattern, but in the "Rebofa" lamp, which has only recently been introduced, the carbons are arranged vertically above one another. Both lamps are provided with gravity feed mechanisms, and the usual shunt and series solenoid control of the arc.

In Fig. 1, which represents the lamp with converging carbons, only one of the two carbons is visible, the other being immediately behind. Both carbons are suspended by a chain over the sprocket wheel *A*, to which is geared a train of wheels ending in the fan-wheel *B*. The carbon holders are weighted so that the carbons tend to descend, but are prevented from doing so by the catch on the end of the lever *C*, which engages with the wheel *B*. At the other end of this lever is a plunger controlled by the shunt and series solenoids, *E* and *F* respectively. When the arc becomes too long, the plunger is drawn down by the shunt solenoid, and the wheel *B* is released. The carbons are then allowed to feed until the plunger rises under the influence of the series solenoid, causing the lever *C* to engage again with the wheel *B*. In the intervals between feeding, the length of the arc is controlled by the rod *D*, which, by means of a sliding collar just above the economiser, moves one carbon towards or away from the other, according as to whether the current is below or above the normal. The mean position of the plunger is gradually lowered as the carbons burn away, until the limit is reached. Feeding then takes place. A "blow" magnet *M* is provided for the purpose of spreading out and steadying the arc, and keeping it at the cores of the carbons. The winding on this magnet is in series with the arc, and the series solenoid. The economiser itself is of fire-clay, held in a cast-iron ring. It can be readily renewed, and does not fall out if fractured. Air enters the globe at the bottom round the sides of the ash tray, which can be seen in the illustration, and escapes out of holes in the spun metal collar supporting the globe. The mechanism is completely separated from the arc chamber, but as a further precaution against corrosion, all metal parts are nickel-plated. For series working above 120 volts substitutional resistances must be used, but these are kept separate from the lamps. The pressure across the arc is 48 volts. When used with cored flame carbons a 34-in. 12-ampere lamp burns 10 hours on one pair of carbons, and a 41-in. 12-ampere lamp about 20 hours.

The "Rebofa" lamp with vertically arranged carbons is illustrated in Fig. 2. The two carbons are connected by a chain passing over the sprocket wheel *A*, which, as in the "Prima" lamp, is geared to a train of wheels ending in a fan-wheel *B*. In this case, however, the clockwork is pivotted on the axle *P* of the sprocket-wheel, and the lever *C* of the regulating gear is connected by a system of smaller levers to the clockwork frame. When the arc lengthens, the pressure increases and the shunt solenoid *E* lifts the plunger, and thus rocks the clockwork frame to the left. This brings the two carbons a little nearer together. As they burn away, the clockwork is rocked still more to the left, and finally the fan-wheel *B* is brought out of contact with the fixed catch *R*. The mechanism is thus released and feeding takes place until the series coil, by drawing down the plunger, again causes the fan-wheel to be locked. An interesting point in connection with



Scale: One Quarter Full Size.

FIG. 1.—THE "PRIMA" LAMP.

Digitized by Google

the air dash-pot provided, is that the piston is made of graphite, thus avoiding any tendency for it to stick.

The arc in this lamp is very short, and as is evident from the above description of the mechanism, the variation in the length of the arc is also very little. Feeding takes place at very frequent intervals, but the carbons are moved together only a very small amount at each

Scale: One Quarter Full Size.

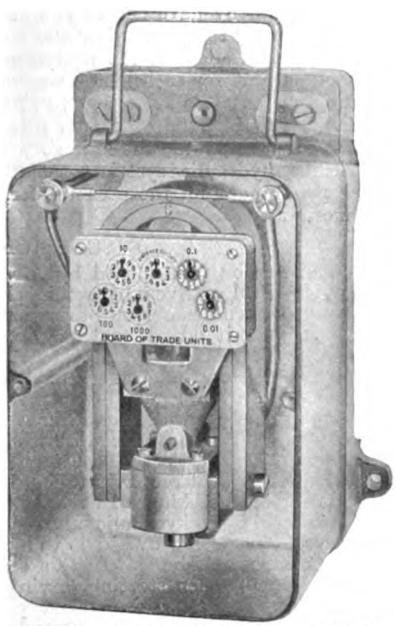
FIG. 2.—THE "REBOFA" LAMP.

feed. These conditions tend towards regular burning with a consequent steadiness in the light emitted by the lamp. The ventilating arrangements are similar to those adopted in the case of the "Prima" lamp. The economiser is of fire-clay, supported, as shown, by a cast-iron ring. No "blow" magnet is necessary in this pattern of lamp. The carbons used are of special manufacture, with large impregnated cores surrounded by a comparatively thin shell of pure carbon, and owing to the disposition of the carbons the arc burns steadily from the cores, having no tendency to burn from the hard carbon shell. The light is stated to be of a soft white colour, suitable for colour matching. Carbons giving a yellow light can be used if required. As the voltage across the arc is so low, six of these lamps can be run on a 200-volt circuit. A 34-in. 12-amp. lamp burns 18 hours on one pair of carbons, and a 40-in. 12-amp. lamp, about 25 hours. The 40-in. lamp, when provided with 8-amp. carbons, burns 22 hours. The chief advantage claimed for this type of lamp is that a greater distribution of light in a horizontal direction is obtained than with the converging carbon flame lamps, thus rendering the lamp particularly suitable for the lighting of streets and other open spaces. Both the above lamps can be had for either continuous-current or alternating-current circuits. In the case of continuous-current lamps, the larger positive carbon is placed below.

RECENT DEVELOPMENTS IN ELECTRIC LAMPS

ON Monday last, at the Royal Society of Arts, Mr. Leon Gaster delivered the first of a series of four Cantor lectures on "Modern Methods of Artificial Illumination." After calling attention to the importance of preserving the eyesight by the use of efficient and correct methods of illuminating, the lecturer briefly summarised the recent history of the incandescent lamp, and pointed out how the efficiency or specific consumption had been reduced from 3·5 watts per candle in the carbon lamp to only a little over 1 watt per candle in the latest tungsten lamps. To illustrate the difficulties met with in the manufacture of metal filament lamps, the shadows of different makes of lamps were projected on the screen and the current switched on and off. The expansion of the filament on switching on was clearly shown, and the necessity for resilient supports was emphasised. Mr. Gaster next referred to the misleading statements made by many firms in pushing the sales of their lamps, and expressed the opinion that the excessive claims made in some cases did much harm to the industry. He advocated co-operation between the lamp manufacturers and the central station authorities, as was effected in America, to ensure that the consumers obtained suitable and reliable lamps.

Before turning to the latest developments in metal filament lamps, the lecturer stated that much had been done of late to improve the carbon filament and render it possible to run it at high efficiency without decreasing its life to too great an extent. Thus, in America, besides the graphitised filament lamps, the "Helion" lamp, which consisted of a core of pure carbon with a coating of silicon, had been developed. This lamp, however, had not yet been produced commercially. In a recent lamp put on the market in Germany, the carbon filament was enclosed in a tube which contained a globule of mercury. When the lamp was on, the mercury was evaporated, and the pressure of the mercury vapour retarded the disintegration of the filament to such a degree that it was claimed that it could be run at an efficiency of under 2 watts per candle without shortening the life to a prohibitive amount. It was now recognised that in many cases it paid to over-run cheap carbon filament lamps so as to obtain high efficiency at the sacrifice of the life of the lamp. The lecturer exhibited a number of different makes of metal filament lamps, several of which had been manufactured in England.



Turning to arc lamps, Mr. Gaster mentioned a few of the more recent improvements, among which were the enclosure of the flame arc as in the "Jandus" flame arc lamp, the successful burning of flame carbons in a vertical position as accomplished in the "Jandus," the "Crompton-Blondel," and the "Rebofa" lamps and an innovation by the Union Electric Co. in a new pattern of the "Excello" lamp, which consisted in the use of a glass chimney surrounding the economiser and preventing the deposit of ash on the globe. This chimney was also moulded prismatic so as to throw more light in a horizontal direction. The lecturer exhibited a few examples of mercury-vapour lamps, including one in which the arc was struck without tilting the tube. In connection with these lamps Mr. Gaster pointed out that the effects of ultra-violet light on the eyes was as yet by no means certain, and that if, as was thought by some authorities, the larger percentage of ultra-violet light emitted by some artificial illuminants was harmful to the eyes, it might be necessary to enclose all such lamps in globes of glass that absorbed the ultra-violet rays

A NEW METER

ON account of their simplicity and their small internal losses ampere-hour meters are particularly suitable in some cases for measuring the units consumed on continuous-current circuits. The British Thomson-Houston Company have developed and placed on the market an improved pattern of mercury ampere-hour meter, a general view of which is given in the accompanying figure. The curve of this meter closely approximates a straight line from the lowest load to full load, the meter starting easily with a load equal to 0·5 per cent. of its rated capacity. Compounding, which introduces hysteresis errors and other troubles, has been rendered unnecessary, as friction has been reduced to a minimum. The continued accuracy of a meter is dependent largely on the ratio of the driving torque to the weight of the moving element, and in this meter a very high ratio of torque to weight has been attained.

The principle underlying the action is that of an ordinary electric motor, the permanent magnet providing the magnetic field in which a copper cup, inverted over one pole of the magnet, acts as the conductor or armature. Commutation is effected by the mercury in which the cup is immersed. The current is led into the mercury bath at the top and out at the bottom, passing down the side of the cup between the two poles through the strongest part of the magnetic field.

B.T.-H. AMPERE-HOUR METER WITH COVER REMOVED.

The meter is connected across a shunt in the main circuit (seen at the top of the illustration), and is calibrated by altering the resistance of this shunt, and not by distorting the magnetic field, as the former method gives the most permanent calibration. It is stated that mercury friction, which is so detrimental to the accuracy of most mercury meters, has been practically eliminated by working with very high torque and strong braking forces. The mechanical friction is also very small, owing to the extremely light pressure on the jewelled bearing. This is obtained by counterbalancing the weight of the moving element by the thrust of the mercury, thus ensuring long life for the pivot and jewel. The total losses have thus been reduced to an extremely low figure.

The mercury sealing device is carefully designed, and when sealed for transportation the packing securely clamps the spindle and completely fills the air-space around it. This renders it impossible for the mercury to leak out. All parts of the meter are made of metal, which will not warp with changes of temperature. In the electrical circuit all joints are soldered. The relative resistance cannot, therefore, change through contact surfaces oxidising; the calibration, once made, is consequently permanent for all practical purposes. These meters are calibrated to read B.O.T. units at any specified pressure up to 600 volts.

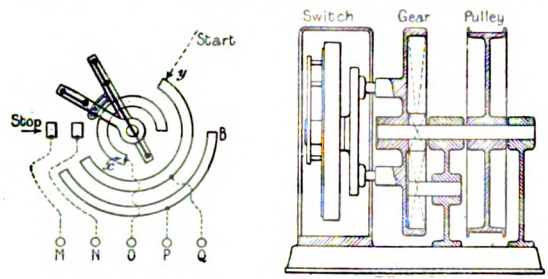
ELECTRICALLY-DRIVEN HYDRAULIC PUMPING PLANT AT THE BRISTOL DOCKS

MR. W. A. CLATWORTHY read a Paper on Monday, February 1st, before the Newcastle Local Section of the Institution of Electrical Engineers, in which he described the electrically-driven hydraulic pumping plant which has recently been put down at the Bristol docks.

Until quite recently this work has been done by two steam reciprocating pumps, automatically controlled in the usual way by the movement of the accumulator. Among the considerations which led to the substitution of electrical driving, in addition to the high efficiency of electric pumping, was the condition of the boilers and the fact that the Bristol Corporation were supplying electric current at favourable rates. The first electrically-driven set was placed between the two steam sets. When this set of pumps had been set to work, one of the steam sets was removed, and the second electrical set of pumps was installed. Finally, the second set of steam pumps was removed, and the third electrical set put in its place.

The new pumps, which were to the specification of Mr. W. W. Squire, the Bristol Docks engineer, and which were made by the well-known firm of engineers, Messrs. Fullerton, Hodgart & Barclay, Paisley, are of the duplex differential ram type, giving a very uniform delivery of water and having a fairly uniform turning effort. The pumps are of the outside packed plunger type, each pump being single-acting on the suction and giving a double-acting discharge. Each set of pumps really comprises two pumps working from cranks set at 90°. The rams are 3⅝ in. and 5⅛ in. respectively by 18 in. stroke, delivering 150 gallons of water per minute, against an accumulator pressure of 750 lbs. per square inch when running at 60 revs. per minute. The suction pipe for each set is 6 in. diameter, branching to 5 in. diameter at each pump suction valve box. The delivery pipe is 4 in. diameter from each pump, coupled to a 4 in. pipe joining the main discharge pipe. The ram of the jack pump is 7½ in. diameter by 18 in. stroke single acting, delivering not less than 27·6 cub. ft. of water per minute against a head of 15 ft., and drawing from the dock with a suction head of 5 ft. at 60 revs. per minute.

The motors are by Messrs. J. H. Holmes & Co., of Newcastle-on-Tyne, 6-pole, open type, with three bearings, designed for a normal speed of 240 revs. per minute, 500 volts, but arranged to run up to a maximum speed of 360 revs. by means of field regulation. The motors are shunt wound and capable of easily giving 125 b.h.p. normally and 150 b.h.p. as an overload. The efficiency is 91 per cent., giving a fairly straight "curve" over a good range of load.



A single reduction of machine-cut double helical gear, running in oil, is used between each motor and set of pumps, with a ratio of 1 : 6. The switching apparatus consists of a switchboard in the pump house, and of three relay switches in the accumulator house.

The starting switch is of the long-screw type with about 50 contacts. The sliding contacts, four abreast, are carried from a travelling bridge worked up and down by the screw. The screw is rotated by a small reversible 250-volt Lundell motor through triple-threaded wormgear. The usual time occupied is fifteen to sixteen seconds, but the return of the starter is quicker. The screw starter contains a lever switch, which is closed mechanically by means of a tappet operated from the travelling bridge. This lever is held on magnetically, thus providing a no-voltage release in the event of the supply failing. A relay circuit is made by this lever in its "off" position so that the starter is automatically returned to its initial position on the resumption of the current supply. The pilot circuit is kept quite distinct from the main circuit, and has its own double-pole fuses, and no-volt release double-pole switches. The field regulating switches for the pump motors are fixed at the tops of the panels, and are of the solenoid type with oil dashpots for retarding the motion both in raising and lowering the speed. There is no permanent step for speed regulation between 240 and 360 revs. The point where this increase of speed shall take place is, of course, determined by the movement of the accumulator, but the screw starter is provided with special contacts in its full "on" position, which prevents the field regulating switch from rising until all the starting resistance has been cut out, and thus ensuring that the motors shall start with full field srength, no matter how rapidly the accumulator may be falling. The pilot motor which operates the starter is controlled in both directions of rotation by small solenoid switches without the use of starting resistances, the connections thus being very rapid. There are two of these solenoid switches, one for starting up and the other for returning the starter to its initial position; they are electrically interlocked so that only one can operate at a time.

D

Digitized by Google

Owing to the limited capacity of the transforming station from which the current supply was drawn, it was necessary to provide that not more than one set of pumps should start at a time. This could not conveniently be arranged from the accumulator switches, because at times the demand for power was so large and the fall of the accumulator so rapid that otherwise it would have been impossible to prevent a second set of pumps starting before a first set had been fully started. Special contacts, therefore, were placed at the ends of the starters to provide for this and in the relay circuit of the solenoid switches belonging to the pilot motor. As a general rule two sets of pumps deal with the load satisfactorily, and although

FIG. 1.—ROTARY ACCUMULATOR SWITCH.

the plant thereby has practically a spare set of pumps, yet all three sets are kept in working order, and do their share of the load in turns. A three-point six-way grouping switch is mounted on the switchboard so that four combinations are possible.

In the accumulator house are three rotary switches controlling the relay circuits of the pilot motor on the starting switches. These switches are rotated by wire ropes from the accumulator. Each accumulator switch is mounted on a marble base and fitted in a cast-iron box; the switch spindle is positively driven from the pulley and gear through pottery insulators on pins forming a kind of flexible coupling highly insulated. The fixed contacts are arranged in rings around the spindle; the movable contacts are of the plunger type. The switch has two levers which are adjustable relatively to one another in an angular direction for

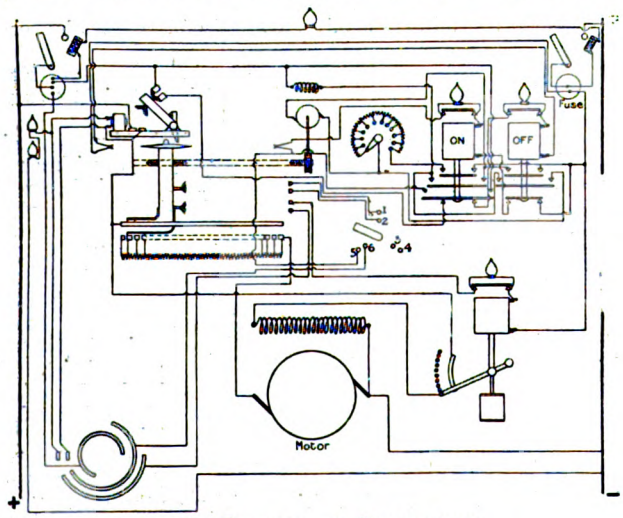

FIG. 2.—DIAGRAM OF CONNECTIONS.

varying the period between starting and stopping. The total angular movement of the switch corresponds exactly with the total travel of the accumulator. To set the switch levers in the first instance, it was only necessary to slacken the wire rope and move the pulley round.

In order to reduce the frequency of starting and stopping as much as possible when two sets of pumps were at work, it was necessary to so adjust the switch-levers that the second set of pumps not only started after but also stopped before the first set working in conjunction with it.

It will be seen from the diagram of connections that when rings *x* and *y* on the accumulator switch are connected, current excites the solenoid of the pilot motor switch for starting the pumps; it may happen at such a moment, however, that the demand for power suddenly ceases, and the first few strokes of the pump cause the accumulator to rise and consequently the lever to fall away again from contacts *x* and *y*, so in order to prevent the solenoid switch breaking circuit and thus causing the starter to remain in an intermediate position between "off" and "on," special contacts are provided by which the circuit to this solenoid, when once made by the accumulator switch, is maintained until the starter has reached the limit of its travel.

It will be seen from the foregoing that it is quite simple if preferred to put the relay automatic system out of action altogether. The starters would then be started up by hand, hand-wheels being provided at the end of the screws and the pumps run continuously, the water being by-passed in the ordinary way at the top limit of accumulator travel.

From observations of the plant in working it was found quite common for a set of pumps to start and stop as often as 20 to 24 times in an hour, and, again, a set has been known to run for four or five hours without stopping. The work is very variable, and depends on the demand for power for several swing-bridges, lock-gates, cranes, &c.

When the first set of electric pumps had been installed it worked quite satisfactorily for some time, sharing the load with one of the steam sets.

Under tests conducted by the Bristol Docks officials, an efficiency of 82 per cent. was obtained, reckoned upon the displacement of the rams against the amount of current used by the motors.

Mr. Clatworthy gave one or two additional pieces of information concerning the plant after the conclusion of his Paper, and showed lantern slides of the equipment. He mentioned that the starting current for each motor was about 175 amperes, and the running current was from 100 to 120 amperes. With two sets of pumps running, the maximum rate of fall of the accumulator was 11 ft. per minute; the leakage which is constantly occurring in such a hydraulic system accounted for an actual drop of 1 ft. per minute on the accumulator, this figure not being at all excessive.

DISCUSSION.

The discussion was opened by Mr. ANDERSON, who referred to an electrically-driven hydraulic plant equipped some eight years ago, when some motor-driven pumps in a shipyard were equipped with standard controllers, each of which was driven by a motor with a pawl and ratchet arrangement, operated by tappet switches on the accumulator. In another pump the drive was obtained by a squirrel-cage motor, and the pump worked on a bye-pass. It was found, however, that it took as much current to send the water through the bye-pass as into the accumulator owing to the constant closing of the valve. A special valve was therefore installed, having a lift for a specified period to avoid checking. In another case, a standard controller was operated by a hydraulic ram. The admission of water to the ram at either side caused it to move a rack and pinion gear on the controller spindle. In this case the water was shut off from the pump when starting, saving the severe current-kick on the motor due to starting against pressure. In an installation such as described by Mr. Clatworthy, the relay gear for each set seemed an expensive item. If one set of pumps were run steadily on the bye-pass, a saving of capital of £150 to £200 would probably be made, and the lost load would only be 15 per cent. to 20 per cent.

Mr. HANKS noted that whereas the pump motors were called in to start on load they were shunt-wound, and asked whether they would not stand up to their work better if they had a few series turns. With regard to the system of speed variation by shunt regulation, did the small arm of the field rheostat, on commencing to rise, continue to the top of its motion, or could the speed be maintained on any intermediate step of the shunt-regulating resistance? The panel controlling such a drive was of the solenoid control type with solenoid switches. A strong trigger was pulled on the second or third step, corresponding to about one-third speed of the motor, and the relief valve descended gradually against a dashpot, the motor thus being brought up to its work gradually. At full speed the valve was fully closed.

Mr. POCKSON was under the impression that the Bristol Corporation had an alternating current as well as a direct-current system, and as a transforming sub-station had been installed for this supply he did not see why direct-current equipment had been adopted, in view of the extra capital expended in a sub-station.

Mr. LAW suggested that if the pumps could be started on a bye-pass the fifteen seconds taken for starting could possibly be reduced to three or four seconds, as in a pump of this description the inertia of moving parts was practically limited to the armature of the motor. What would happen supposing that the small motor did not get the starter back again to its "full-off" position before the pump-set was required again?

Mr. HIGGINBOTTOM remarked that the engineer to the docks specified starting against full load, but Messrs. Holmes had built several to work with bye-passes.

Mr. TURNBULL asked why the current was transformed. He could understand it if the direct current was for the purpose of also supplying a stand-by battery. In cases where only one installation was fed from such a sub-station it would be possible to reduce the volts to zero and then start up the pumps, bringing the volts up on the motor generator without the use of starting

Digitized by Google

resistances. A reversing booster could be used to reduce pressure on starting up the pumps from a battery.

After a few questions by Mr. Longman, Mr. Law, and Mr. Taylor,

Mr. CLATWORTHY said, in reply, that bye-pass arrangements were very usual, and involved less prime cost. In one case he knew of, the bye-pass was left open till the motor reached full speed. On the last step of the starter a current to a solenoid closed the bye-pass, whose action is checked by a dashpot. The load on the motors was by no means steady, as the duty required depended on the tides and the variation of business. The pilot motor gave no trouble on sudden reversal. With regard to the shunt-wound motor, there was no great armature reaction at starting, and the field was thoroughly saturated. In the shunt regulation there was no intermediate position between bottom and top positions of the rheostat arm, *i.e.*, the speed varied from 240 to 360 r.p.m. only. This was accomplished in five or six seconds. The sub-station referred to already existed for other pumps, crane motors, arc lighting, &c. No battery was installed.

ELECTRIC POWER SUPPLY IN SCOTLAND

A CONFERENCE of Scotch municipalities was held in the City Chambers, Glasgow, on Wednesday, February 3rd, to consider the proposals of the North British Electric Power Syndicate, Ltd. Representatives were present from Aberdeen, Alloa, Ayr, Dundee, Edinburgh, Falkirk, Glasgow, Govan, Greenock, Leith, Motherwell, Oban, Paisley, Partick, Perth, Stirling, Wishaw, Convention of Royal Burghs, County of Lanark, and County Councils' Association. The Hon. The Lord Provost of Glasgow occupied the chair.

The letter convening the conference, which was sent out by the Glasgow Corporation, stated that a syndicate has been formed under the name of "The North British Electric Power Syndicate, Ltd.," which proposes to supply, without Parliamentary powers, electrical energy to collieries, railways, factories, mills, tramways, local authorities, &c., even where these are already, or might be, supplied by municipalities within their areas of supply. The Syndicate believe that there is a demand for a cheap supply of electric current, and that the supply already provided by municipal authorities and by electric light companies, operating under statutory powers, is inadequate. It is the intention of the Syndicate to utilise railway tracks for the laying of cables, and it is understood that they have already adjusted with the North British Railway Co. and the Caledonian Railway Co. the heads of an agreement relative to wayleaves for cables. It is pointed out that, under the Electric Lighting Acts, the public and consumers of electricity are protected, and local authorities acting under Acts of Parliament, Orders, and Licences, are supplying under conditions, the breach of which entails penalties. The consumers are protected against illegal preference, but the Syndicate, which has no parliamentary powers, will be under no penalties to its consumers, unless conventional, and no restrictions as to the giving of preference. Having regard to the statutory rights possessed by authorised undertakers to the restrictions and penalties under which they are placed as to the method of giving a supply, and to the charges they may make, and other circumstances, it has been generally understood, says the letter, that, to a certain extent, an exclusive right had been conferred upon them for the supply of electric current within their own areas of supply, and that such exclusive right would be continued so long as such authorised undertakers reasonably met the needs of all the consumers within their areas. The Syndicate, without getting parliamentary powers, and submitting to the conditions imposed by Parliament on electricity undertakers, should not be entitled to compete with authorised undertakers in supplying electric energy.

The letter concludes by pointing out that it is in the interests of supply authorities to preserve their statutory rights, and states that it has been suggested that the conference might consider the propriety of (1) making representations to the Board of Trade with the view of getting a short Act of Parliament passed prohibiting any company or person, unless authorised by the Board of Trade under the Electric Lighting Acts or by Parliament, from distributing or supplying electrical energy for sale within the area of supply of any authorised undertakers; and (2) contesting the rights of the North British and Caledonian Railway Cos. to make and implement the agreement as to wayleaves before referred to.

The chairman, having welcomed the representatives, directed the attention of the meeting to the necessity for united action being taken to conserve the interests of those undertakings which had been commenced in the public interest. After an interchange of views, the following resolution was, on the motion of Depute River Bailie Stewart (Glasgow), unanimously agreed to, viz. :—

"That this conference of representatives from burghs and counties in Scotland, supplying or having the right to supply electricity in virtue of powers conferred upon them by Act of Parliament or by Provisional Order, resolves to represent to the Board of Trade that in the interests of the communities represented by them it is expedient that legislation be passed prohibiting any company or person, unless authorised by the Board of Trade, under the Electric Lighting Acts, or by Parliament, from distributing, transmitting, or supplying electrical energy for sale within the area of supply of any authorised undertakers."

Further resolutions were passed authorising the Town Clerk of Glasgow to forward the above resolution to the Board of Trade, and pledging the authorities represented at the conference to share the expense incurred in connection with any litigation.

THE NEW SECRETARY OF THE INSTITUTION OF ELECTRICAL ENGINEERS

AT the Institution of Electrical Engineers, on Thursday night, it was announced that Mr. P. F. Rowell has been appointed Secretary of the Institution, to take the place of Mr. Lloyd, who has been appointed Secretary of the Iron and Steel Institute. Mr. Rowell, who has up to now filled the post of Assistant Secretary, assumes his duties at once. As a member of the secretarial staff since 1901, he has been popular with all the members who have come in contact with him, and his appointment as Secretary meets with general approval.

PERCY FITZ-PATRICK ROWELL,
The new Secretary of the Institution of Electrical Engineers.

Mr. Percy Fitz-Patrick Rowell was born in London in 1874. He is the son of the late Patrick Irvine Rowell, of Aberdeen, and grandson of the late Dr. Percy Fitz-Patrick, who, as Surgeon of H.M. 51st Regiment, went through the Peninsular and Waterloo campaigns, and was subsequently for many years physician to the English-speaking colony at Nice. Mr. Percy Rowell received his earlier training at the Royal College of Mauritius, where he obtained a valuable mathematical scholarship in 1892, with the gold medal for that subject. From 1893 to 1897 he continued his studies in mathematics and physics in London at Messrs. Wren and Gurney, and at King's College. His general business experience was acquired in the City of London, where he was employed for four years in the offices of engineering firms.

In 1901 Mr. Rowell was appointed principal assistant to the late Mr. W. G. McMillan, Secretary of the Institution of Electrical Engineers, and during the last five years he has filled the position of Assistant Secretary.

He is a good linguist, and his intimate knowledge of the affairs of the Institution, the share he has had in the executive work for many years, and his large personal acquaintance among the membership all qualify him for the post he is about to fill. The Institution has always been fortunate in its choice of secretaries, and there is every reason to believe that the appointment of Mr. Rowell will be no exception.

METHOD IN INVENTION

AT an informal meeting of the members of the Newcastle Local Section of the Institution of Electrical Engineers on January 18th, a Paper by Mr. C. Turnbull (Borough Electrical Engineer, Tynemouth), entitled "Concerning Method in Invention," was read and discussed. Commencing with the cryptic utterance, that progress was the achievement of the impossible, Mr. Turnbull proceeded to argue that invention was evolutionary rather than revolutionary. He then outlined a series of rules or "operators" relating to different stages in the development of invention. These were classified as follows :—(1) Selection and chain operator; (2) equivalence operator; (3) change of position operator; (4) addition operator; (5) omission and direct operator; (6) change of proportion and increased function operator; (7) separation operator; (8) combination operator; (9) transference and distribution operators; (10) the converse or reverse operator; (11) the constraint and freedom operator; (12) the relay operator.

Selection and Chain Operator.—The selection and chain operator works by setting forth clearly the parts on which the inventive faculty may work. In other words, the parts on which he

Digitized by Google

may operate are set out like so many links in a chain, each link in turn being examined to see what can be done with it. Consider the leading-in wires of an incandescent lamp. To make them satisfactory from all points of view one may operate on the following: (1) The material of which the wire is made; (2) shape of same; (3) constitution of the glass; (4) material or cement round the leading-in wires. A vast amount of work was done on 1, 3, and 4, but 2 was neglected until Bastian tried flattening out the wires. Then it was found that an air-tight joint could be made with flat copper wires. Probably this would have long ago been found out had people only been accustomed to write down the possible parts for working on and method of working same as above.

Equivalence Operator.—It was pointed out that the process of invention might be divided into three parts: To do the thing at all, to do it well, and to do it well and cheaply. The use of the operators will frequently suggest methods which may appear ridiculous, but once some kind of a method has been proposed, one may vary it by getting equivalent methods which will work better. Also, when a machine has been made to work fairly well, vast improvements may often be carried out simply by getting equivalent methods of working. Thus the carbon filament of the electric lamp was originally made from a carbonised thread or vegetable fibre. This did not work at all well, but a great improvement was made when an equivalent thread was formed by squirting.

Change of Position and Addition Operator.—Much invention may be done simply by changing the position of parts, or of operating forces. Consider the steam turbine. The steam flow may be either radial or axial, or it may come on to the turbine in the style of the Pelton wheel. The turbine may be either vertical or horizontal. The low-pressure end may be separated from the high-pressure end completely or incompletely by merely having a bearing between the two parts. Starting from this it will be found that pretty well every design of turbine on the market and a number of designs not on the market can be deduced from two or three primitive forms by combining together and changing the number of the expansions. No doubt it would have been very awkward for patentees had some industrious person worked out and published every possible arrangement and combination of the steam turbine in its various forms. Nevertheless, if these various forms have to be found out, it would be better that they were discovered methodically.

Omission and Direct Operators.—Pringle's patent trolley wire suspension provides an example of invention by omission. Previous to this patent catenary suspensions had been in use. Omit the centre part of the catenary wire and we get Pringle's suspension. Great improvement was made to enclosed arc lamps when the inner globe was omitted. Indeed, many people who have the old-fashioned arc lamps on their hands sorrowfully wonder why the inner globes were ever fitted at all.

Separation and Combination Operators.—Much invention consists in the mere combination or separation of parts. Thus, in electrical meters the braking and motor magnetic circuit are combined in the latest Hookham, whereas, previously, two magnets were used for these purposes in the Ferranti. In the previous Hookham one magnet was used for both purposes, but the circuit was separated out into two parts. The Merz-Price protective device forms an interesting example of combination. The previous method of protecting a cable was by a circuit-breaker at each end. In the Merz-Price arrangement the effect of the action at the ends was combined, and the breakers were operated by the difference between the currents going in at the ends.

Transference and Distribution Operators.—We may also instance the use of a beam of light for magnifying purposes. Originally invented by Lord Kelvin for the galvanometer, it has now been used for all kinds of purposes where similar magnification is needed.

The Converse or Reverse Operator.—The electro-motor was a case of reverse action being deduced from the dynamo. The slide rule provides another case. Normally, one works out geometrical problems by means of mathematics, but with the slide rule one gets the geometrical relation first and the mathematical calculation is obtained from it. Whenever any geometrical problem is solved, one must remember that it may be used conversely or reversely in this manner.

The Constraint and Freedom Operator.—The greater part of mechanics has for its object the constraining of parts to cause them to carry out their functions in an unvarying manner. Frequently an operation is carried out by hand, and a machine has to be constructed which will carry out the same functions, only with the difference that it is compelled to act always in the same manner, whereas the hand can accommodate itself to varying circumstances. Occasionally machines become too constrained, and it becomes necessary to free them by what I have called the "Freedom Operator." The commonest illustration is provided by the ordinary draughtsman who delights to design machines which cannot easily be got at for repair. It becomes the duty of some more practical man coming along later to free the machine from the various unnecessary constraints imposed on it by the original designer.

The Relay Operator.—It is not convenient in many cases to operate mechanism directly, and in this case the relay is of use. It should always be kept in mind when problems of this kind are to be solved. Wireless telegraphy provides abundant illustrations of the use of the relay operator.

DISCUSSION.

Mr. C. FARADAY PROCTOR had come across many cases where, if the inventor of an article had been familiar with the system, it would have been almost impossible to have patented anything which would have reversed the same grounds.

An important matter was to realise when one had reached the critical point in a design, and, mentioning the "S" lamp-holder, Mr. Proctor remarked that in designing this he set out to get the maximum length between the contacts, with the result that without making any special effort he secured an extremely high insulation. He advised inventors to have faith in their own ideas, and this had been responsible for many successful inventions.

Mr. F. TREMAIN said that it was unkind to suggest that if Mr. Turnbull's system had been followed many present-day inventions might have been invented 30 years ago, because there was no doubt that inventors had always, more or less, followed some such course. According to this system, it appeared that all one had to do was to write down all the possible ways of doing a thing, pick out the best, and then become a millionaire. Mr. Tremain suggested that Mr. Turnbull should turn his methods to inventing a telephone repeater, for which, he understood, a million dollars had been offered in America.

Mr. H. W. CLOTHIER noted that the Paper did not touch on the question of necessity, and this was just the point which so many inventors overlooked. Mr. Turnbull should not be surprised at manufacturers not jumping at every invention which was offered to them. After all, every manufacturer had a staff of inventors in his drawing office, and their time was utilised to the best advantage, because they were put to work on an invention only when there was a demand. Another point was that in many cases taking up another invention would clash with one of their own, and he instanced the case of his own firm, who refused the offer of an invention relating to slow-motion motor-starters simply because they already had a starter on the market which automatically allowed a gradually-increasing current to pass, and that without any mechanical assistance. He pointed out that the Merz-Price system was not a combination of two circuit-breakers, but was an entirely new method of protecting ring mains, and it was necessary in order to meet a new set of conditions.

Mr. G. RALPH agreed with the previous speakers that, according to this Paper, it was only necessary to write everything down in order to become a successful inventor, but he also agreed that it was very necessary to choose the critical moment in which to bring forward an invention. In his opinion every inventor used exactly the methods set forth in the Paper, although probably in different order.

Mr. J. P. SLEIGH considered that all the previous speakers had missed the point of the Paper. In inventing, no doubt, one thought of all possible means, but it had been left for Mr. Turnbull to lay down systematic rules, and he considered the Paper valuable from this point of view.

Mr. A. L. E. DRUMMOND remembered that 25 years ago it was impossible to invent a new telephone transmitter, because every possible and impossible idea was covered by patents. In his opinion the granting of wide patents for transmission had retarded telephone development in this country to a very great extent.

Mr. TREMAIN, in a further contribution to the discussion, recalled some experiences with the Hughes telegraph, and he pointed out how an invention might seem perfect under one set of conditions and still prove a failure under other circumstances.

MR. C. TURNBULL, in his reply, said that he had thought of these methods for the last 15 years, and he had found the system of operators to be of great practical use. Everything pointed to the early inventors not having been methodical, and he mentioned the case of boilers, new and obvious forms of which were frequently being "invented," notwithstanding that one could sketch out every possible form of boiler by combining in various ways a few simple units. Touching on necessity, Mr. Turnbull pointed out that the necessity for many things had existed for years before they were invented. He considered that inventors required protection, and they could do a good deal for themselves by safeguarding every possible way of getting round their inventions. He thought that it would pay large firms to retain a staff of men to do nothing else than to get out possible ways of doing a particular thing—in this way, not only would they safeguard their patents, but they would have a mass of material from which they might draw ideas which would pay for the special staff over and over again.

THE G.B. SURFACE-CONTACT SYSTEM AT LINCOLN

THE Paper on the working of the G.B. surface-contact system at Lincoln by Mr. Stanley Clegg, which was read at the London meeting of the Institution of Electrical Engineers (see ELECTRICAL ENGINEERING, January 21st, page 61), was further discussed in Leeds on January 27th.

The discussion was opened by Mr. W. M. ROGERSON (Electrical Engineer and Tramways Manager, Halifax Corporation), who congratulated the author upon the low current consumption obtained, but thought that in comparing the maintenance expenses with those of other systems, it should be borne in mind that the Lincoln line has only been running about two and a half years. He also asked for some further particulars with regard to the adhesion that might take place between the carbon contacts and the cable. In making comparisons with other lines regarding current consumption, it must be remembered that the Lincoln line is practically without gradients. He envied the author in having Sundays to effect repairs on, and took up the view that the noiseless running of the cars was a positive disadvantage.

Mr. W. N. Y. KING (Tramway Department, Sheffield Corporation) agreed that comparisons as regards maintenance costs should only have been made with systems that had been running three years or less, and showed a table of 19 such systems, which gave an average of 0·79d. per car-mile, against Mr. Clegg's 1·25d. for maintenance. The leakage was much greater than with an overhead system, where in Sheffield it did not usually exceed 0·2 amperes. There were, however, certain points about the G.B. system which would be much worse in towns where there was a continuous road traffic. There would be worse contact on the surface studs through ice and snow, or even excessive dirt lodging there and putting the chain link out of contact. In hot weather the bitumen would be apt to get soft, and the heavy traffic would have the effect of driving the studs down into the ground and upsetting the adjustment of the contact maker. Finally, he thought that the system itself was a very excellent one. Compared with any other surface-contact system, it was a great advance in simplicity and cost of construction, and it perhaps equalled the overhead system in reliability and safety. As regards noise and unsightliness of poles, &c., there was no doubt that it had something to commend its adoption.

Mr. J. F. FAWCETT pointed out that there was a good deal of heavy traffic, including traction engines and the like, in Lincoln. The number of live studs experienced had at first surprised him, but it only worked out to 2·25 per cent. per annum, and this would probably be reduced. This was, however, not excessive, and, considering the way in which tower wagons had to be kept ready for use the trouble was probably not greater than with overhead equipment.

Mr. J. J. MCMAHON, in a written communication, put it that the choice rested between this and the conduit system where overhead equipment was objected to. It was, he thought, fortunate that the G.B. system was first tried on a very small scale, on level lines with few junctions and very little traffic, as the methods described would, in his opinion, never be tolerated on a large and busy system. Something must be done in order to avoid the necessity for the pulling and turning of the cable mentioned and the cable itself would be useless in the corrosive atmosphere of a large manufacturing city or town if made of iron wire covered with iron tubes as described. The galvanising afforded practically no protection, and in a few months the surfaces would be covered with rust. It ought to be a simple matter to clamp some form of copper or gunmetal seating on the cable at each contact point, and so eliminate all damage to the cable. As regards dangers from the wires, in Manchester there had been only five wires down during the past five years, and the wire can be generally seen and avoided. During the period, August 24th, 1907, to September 7th, 1908 there were 40 live studs at Lincoln and this meant that against the five live wires down Manchester would have had *pro rata* something like 20,000 live studs had it been equipped with this system.

Mr. W. J. BENTON wished for further information as to how it was possible to repair live studs in so short a time as described by the author, considering that they were laid in bitumen and would be difficult to remove. There was one important point with regard to the overhead system that was very evident to those in Leeds, and that was the relaying of the track. He questioned whether any surface-contact system would lend itself to relaying as does the overhead system. The temporary line is laid alongside the original track, and the trolleys take the wire as before. Of course, the author had not had it to do as yet, but it would be interesting to know if there were any real difficulty in this respect.

Mr. H. E. YERBURY (Corporation Tramways Manager, Sheffield) asked a few questions on the insulation tests. The system appeared to be satisfactory in a town where the conditions were favourable, but he was afraid that some of them who had rather larger undertakings to look after, with very heavy cars, complicated crossings, and a very large current consumption, would hesitate before deciding on a surface-contact system.

Mr. STANLEY CLEGG, in reply, agreed with Mr. Rogerson that reliable comparisons of upkeep could only be made between systems that had been in use for several years, but suggested that if the results at Lincoln were compared with the results obtained on some of the earlier overhead lines, the former would prove much more satisfactory. The wear on the original type of cable installed was due largely to the indifferent contact between the plain surface of the carbons and the corrugated surface of the stranded cable. The carbons eventually took the impression of the strands of the cable, but before this could happen, a considerable burning of the cable had taken place. Several of the worst burns on the cable were caused by trouble with the insulator supports for the car magnets. At one point, one of the earthed insulator supports, and one of the live magnet supports, were within a few inches of one another, and this on wet days resulted in a dead short taking place across the hangers. Insulated bolts, similar to those used for straining up span wires on the overhead system, were substituted for the insulator supports at these points, entirely getting over the difficulty. With the new plain surface cable it was not necessary to move the cables more than once every 12 to 15 months. Replying to Mr. King, who thought that dirt would make a difference to the collecting apparatus, the author said that this was not so, as he had driven cars when the road was covered with a layer of mud; the chain, however, found the studs without fail. There was no likelihood of heavy traffic forcing the studs down below the road level, as the stud head had a direct bearing on the bottom of the slot cut for it in the granite block. He could not agree with Mr. McMahon that in a properly ventilated conduit a galvanised iron cable would be rusted over in twelve months, no matter how bad the atmosphere of the place, as he had found that electrolytic action at a point where a sagging cable had been in contact with water in the conduit was the only cause of rusting of the cable. With regard to the question of track replacement, there was no doubt that this could always be done very much easier with an overhead system tramway, owing to the ease with which the traffic could be worked over temporary track without making any alteration to the supply. With the "G.B." system it would be necessary for the work to be done when the cars were not running, though on a small system like that at Lincoln, much could be done in the day-time without disorganisation of the service. The insulation test referred to by Mr. Yerbury was taken in exactly the same manner as on the overhead system, the line being charged, all cars having their magnets unexcited, to correspond with the trolleys being taken off the overhead line. The test was, of course, the resistance between the live cable and earth, as the stud switchpiece could only be tested separately.

Institution of Electrical Engineers.—Acting under powers conferred upon them by the Articles of Association, the Council of the Institution have unanimously elected Mr. A. H. Walton, of the British Thomson-Houston Co., to the seat on the Council, rendered vacant by the retirement of Prof. E. Schwartz. Mr. Walton originally joined the British Thomson-Houston Co. to superintend their work on the construction of the Central London Railway. Previously to that he was Chief Engineer to the Metropolitan Electric Supply Co.

The Electrical Properties of Flames.—A large number of experiments, illustrating the conductivity of the hot gases in and near a flame, were carried out and explained by Prof. H. A. Wilson, F.R.S., on Friday evening last at the Royal Institution. Many of the experiments were exactly similar to those illustrating the conductivity of rarified gases, and the lecturer showed that most of the phenomena could be explained in the same way. Thus the potential across a flame was practically independent of the distance between the electrodes, but was proportional to the square of the current flowing. Again, practically the whole of the potential drop was at the surface of the cathode. Experiments on the conductivity of flames when a metallic salt was placed on the cathode showed that with a given potential, the product of the current and the electrochemical equivalent was constant. This was analogous to Faraday's law of electrolysis for solutions.

Tramways and Light Railways Association.—The twelfth annual general meeting was held at the Gaiety Restaurant at 7 p.m. on Friday last, when the report and accounts for the year 1908 were approved. This was followed by the annual dinner. In addition to a large number of members and their friends, the following were present:—Lord Weardale, Mr. H. J. Tennant, M.P. (Parliamentary Secretary, Board of Trade), Sir H. Jekyll, Mr. A. Shirley Benn (L.C.C.), Mr. E. S. London (Somerset House), Sir Charles Petrie (Chairman, Liverpool Corporation Tramways), Mr. A. R. Smithson (Chairman, Leeds Corporation Tramways), and Mr. H. E. Blain (General Manager, West Ham Corporation Tramways). The loyal toasts were proposed by the Chairman and given with musical honours. The toast of "Our Guests" was proposed by Mr. James Devonshire (vice-chairman) and was responded to by Mr. H. J. Tennant, M.P. "The Association" was given by Lord Weardale, and was responded to by Sir Charles Petrie, J.P. (Chairman, Liverpool Tramways), and by the Hon. Arthur Stanley, M.P. (Chairman). A smoking concert followed.

LOCAL NOTES

BELFAST: *Railway Companies and Motor Omnibuses.*—The Municipal Tramways Association has suggested the holding of a conference in London to consider the clause in the North-Eastern Railway Co.'s Bill, providing for the running of motor omnibuses. The Corporation has decided, however, not to send representatives. So far as Belfast is concerned, they are already protected in this matter. Another factor in the decision was that the expenses of delegates to any such conference would be surcharged by the Local Government Board.

Cavehill and Whitewell Tramways.—At the weekly meeting of the Electrical and Tramways Committee on the 15th inst., a deputation waited to urge the desirability of coming to some agreement speedily with the Cavehill & Whitewell Tramway Co., as they were greatly inconvenienced owing to the want of a connection. Subsequently a recommendation to the Council to enter into a working arrangement with the company for one year on the draft basis already submitted, was defeated, and an amendment to take counsel's opinion on several points raised was passed.

BRIGHTON: *Plant Extensions.*—In connection with the recent recommendation of the Electricity Committee that the tender of Messrs. Babcock & Wilcox, for extensions of the boiler plant, should be accepted at £15,500, the Council has referred the matter back for further consideration, with a request that the Consulting Engineer should report whether this expenditure can be delayed for a year without serious loss, and whether, in regard to the Southwick works, equal efficiency has been obtained elsewhere at less cost. Mr. Arthur Wright has since reported to the Council that the extensions in question are urgently needed.

CHIPPING NORTON: *Electric Lighting.*—The Council have given their consent to the introduction of the Chipping Norton Electric Lighting Order, 1909, by a Company.

CONSETT: *Contravention of Mining Rules.*—A motorman at the Amsterley Colliery has been summoned for a contravention of Special Rule 131 of the Mines Act, which stipulates that no cable shall be allowed to remain under a coal-cutting machine. The defendant having allowed this to happen, the insulation was stripped off, and he received a severe shock. As the case was not pressed, and the man had suffered from the consequences of his act, the magistrates merely imposed the costs of the action.

DUBLIN: *Engineering and Scientific Association.*—The annual dinner of the Engineering and Scientific Association of Ireland was held at the Gresham Hotel last week.

DUNDEE: *Trackless Trolley System.*—The Tramways Committee have had under consideration a report by the Sub-Committee that the trackless trolley system should be introduced as an experiment along the Esplanade. The distance of the proposed route is nearly three miles, and the cost of construction was estimated at £2,700; the feeder cables, £520; and three cars, £2,000. The estimated costs of running were put at between 5d. and 6d. per mile. After some discussion the matter was referred back to the Sub-Committee for further consideration, with an instruction to report upon an alternative route.

DURBAN: *Electric Lighting.*—In his report for December, Mr. J. Roberts, Borough Electrical Engineer, states that there are plain indications that the installation of metallic filament lamps on business premises is having a restrictive effect on the output of the works. The consumption of current for the month of December for electric lighting has been lower than any year since 1904, in spite of the fact that the number of consumers has increased largely. There can be no question that the remainder of the municipal year will see a continued decrease in the amount of electric current used compared with previous years, and not only business consumers, but also private users have effected large savings in their electric light bills by the use of the metal filament lamp.

FINCHLEY: *Street Lighting.*—The Local Government Board has informed the Council that an inquiry will be held shortly into their application for sanction to borrow £2,200 for street arc lighting. At the same time the Board asks to be informed to what extent the Council have considered the cost of public lighting by electricity.

HOVE: *Street Lighting.*—Further experiments are to be carried out with street electric lighting, and 35 additional gas-lamps are to be converted.

HYTHE: *The Tramways Scheme.*—Mr. W. B. Cownie, of the National Electric Construction Co., has addressed a long letter to the Council in relation to the bill for authorising the company to instal the overhead system of traction. He points out that as the surface-contact system, as originally agreed, has proved out of the question, and the conduit system was far too expensive, the only alternative is the overhead system. He admits that the original revenue estimates, although considered fair at the time, were now regarded as too high, and Mr. Cownie reminds the Council that Parliament will want to be convinced that the system can be made to pay, and for this reason he asks the individual members of the Council to consider the matter as a business proposition in order that an agreement may be arrived at.

LONDON: *Shepherd's Bush Exhibition.*—A narrow-gauge electric tramway will be laid round the grounds of the "White City" at Shepherd's Bush on the occasion of the forthcoming Imperial International Exhibition.

London County Council: Tramways.—A difference of opinion has arisen between the London County Council and the St. Pancras Borough Council with regard to whether wood-paving or granite setts shall be used for certain tramways in the district. Some delay is being caused in the work of electrification, and the Highways Committee recommend that an application should be made to the Board of Trade for the appointment of an arbitrator to settle the matter.

Bermondsey: Tramways.—The Council has agreed to the electrification of the Tooley Street to Deptford tramways, but refuses to accede to the request of the London County Council to share any portion of the cost.

Hackney Tramways.—The Borough Council are opposed to the proposed tramway along Victoria Park Road, which is included in the London County Council Tramways and Improvements Bill. The proposed line would be 1¼ miles in length, and would involve extensive street widenings. The actual opposition, however, is based on the opinion that the line would be too far south to meet the admittedly urgent need for greater travelling facilities in the district.

LOWESTOFT: *Energy for Tramways.*—The Electricity Committee recommend that the price of energy for tramway purposes be reduced to a flat rate of 2d. per unit.

MACCLESFIELD: *Electric Lighting.*—The Parliamentary agents for the Corporation have notified that, in respect of the intended application on behalf of the Macclesfield Electric Light & Power Co., Ltd., for an electric lighting Provisional Order, the necessary deposit has not been made, and the application cannot be proceeded with this year.

MANCHESTER: *New Engineering Society.*—The Municipal School of Technology has formed an Engineering Society.

MONTREAL: *Contractors' Association.*—An Electrical Contractors' Association has been formed in Montreal with the avowed object of adjusting trade grievances, keeping members informed with regard to trade conditions, and to raise the standard of electrical construction. The following is the list of officers: President, E. W. Sayer (Sayer Electric Co.); vice-president, J. A. Valois (Chambly Electric Co.); 1st vice-president, M. Rubenstein (Scott and Rubenstein); treasurer, W. B. Shaw (Montreal Electric Co.); secretary, W. A. Stanley; executive committee, Messrs. C. J. Young (Henry Morgan & Co.), J. G. Brock (Collyer & Brock), J. A. Lachapelle (Eastern Electric Co.), J. A. St. Amour, N. Simoneau (Simoneau Electric Co.), C. G. Matthews (Electric Repair and Contracting Co.), Lacasse Rousseau (Canada Electric Co.).

OXFORD: *The Tramway Question.*—Sir Alexander Kennedy, who is advising the Council with regard to their tramways, paid a visit to Oxford on Tuesday.

PORT SUDAN (EGYPT): *Electrical Equipment of Harbour.*—In a memorandum dealing with the Port Sudan, H.M. Consul-General at Cairo says that of the permanent quays, five berths, each 125 metres in length, will be ready for shipping by April 1st, 1909. They will be lighted by electricity, and be equipped with the latest pattern of electrically driven cranes, &c., as follows: Cranes, four 3-ton and one 7-ton electric gantry cranes; electric capstans, two 5-ton and four 1-ton; coal-handling plant, four electric coal-transporters and one electric coal re-handling bridge plant are erected at the coal berths of the quay. The four coal-transporters are capable of dealing with 300 tons of coal per hour. The cranes will be ready by April 1st next, and the coal-transporters by June 1st.

SOUTH SHIELDS: *Tunnel under Tyne.*—The Parliamentary Committee recommend that a petition be lodged against the North and South Shields Electric Railway Bill. This is mainly as a precautionary measure in view of preliminary negotiations being carried on. It may also be pointed out that Mr. Schenk, who is acting on behalf of the promoters of the tunnel, has been informed that the Tynemouth and South Shields Corporation do not see their way to guarantee the debenture interest until the railway is completed and certified by the Board of Trade to be in working order. Mr. Schenk has agreed to this, however.

SOWERBY BRIDGE: *Electric Lighting.*—Representatives of the Yorkshire Electric Power Co. have met the Council with regard to a transfer of their Provisional Order. After a discussion, the representatives of the Company promised that the question of taking over the Order, and also that of supplying current in bulk to the Council, should be considered at the next Board Meeting of the Company on the 29th inst., and that they would let the Council have their decision as early as possible.

SWANSEA: *Telephone Company's Assessment.*—The question of assessing the National Telephone Co.'s undertaking in Swansea upon the aggregate earnings, instead, as hitherto, at a fixed rate of £1 per mile of wire, is under consideration. It will be remembered that the Chorlton (Manchester) Assessment Committee recently established their claim to assess in this manner.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

ABERTILLERY.—The Council invite tenders for two 66-kw. vertical gas engines, and dynamos, suction gas-producer plant, balancer, booster, pipework, and water supply plant, switchboard, poles and overhead conductors, underground cables, feeder, and other pillars and public lighting apparatus. Particulars from the consulting engineers, Messrs. F. H. Medhurst and Brewer, 13 Victoria Street, Westminster, S.W., and tenders by February 26th.

BRIGHOUSE.—The Council invite tenders for a balancing set, feeder cables, and switchboard. Particulars from the consulting engineers, Messrs. Lacey, Sillar, and Leigh, 2 Queen Anne's Gate, Westminster, S.W., and tenders by March 2nd.

DARLASTON.—The Local Government Board has sanctioned a loan of £800 for purposes of erecting the electric lighting wires on the tramway poles, but the tramway company have refused to give the necessary facilities unless the Corporation pay a rent of £380 per annum, and enter into various indemnities. It has, therefore been decided to lay the wires underground and to apply for a loan of £1,700 for this purpose.

DARLINGTON.—The Borough Electrical Engineer recommends the installation of a 500-kw. generator driven by an exhaust steam turbine.

DROYLSDEN.—The Manchester Corporation has in hand a scheme for supplying electricity in this district.

EDMONTON.—The Guardians invite tenders for an electric light and power installation at the new workhouse. Particulars from Messrs. May and Hawes, Consulting Engineers, Caxton House, Westminster, S.W., and tenders by February 24th.

HERNE BAY.—In a report by the Consulting Engineers, Messrs. Lacey, Sillar & Leigh, of London, the following estimates are given of a proposed electricity undertaking: Two 225-h.p. gas-engines and accessories (300 kw.), £3,000; two producer plants for ditto and accessories, £720; four 75-kw. d.c. generators (two on each engine), £900; circulating water-system, pumps, tank, and pipes, £100; pipework other than for circulating system, £50; lifting tackle, £100; accumulators and stands (280 amp.), £550; booster, £150; switchboard and cabling, £600; station lighting and wiring, £70; tools, instruments, and sundries, £100; buildings for engine-house, producer-house, battery, and offices, £2,000; foundations for engines and producers, trenches, &c., £130; provision for sinking well for water, £250; fees and contingencies, 10 per cent., £872; mains and services, £3,397; fees and contingencies, 10 per cent., £339; land, £500; total, £13,828.

LONDON: *London County Council.*—The Council require (1) a 20-ton overhead hand travelling crane, two 1,500-kw. rotary convertors, and six 575-kw. static single-phase air-cooled transformers, for the Elephant and Castle sub-station; (2) high- and low-tension switchgear, &c., at the Elephant and Castle sub-station; (3) wiring and fitting for the Norwood car-shed. Particulars from the Engineer, and tenders by March 9th.

Bermondsey.—Application is to be made to the L.C.C. for a loan of £3,000 for the extension of mains and services.

Stepney.—The Finance Committee of the London County Council has sanctioned the borrowing of £10,000 by the Stepney Council for electricity purposes.

LOWESTOFT.—A 250-kw. generating set is required by the Corporation.

STOCKPORT.—Tenders for the new distributing mains to the Stepping Hill Hospital are required. Tenders to the Clerk to the Union, Shaw Heath, Stockport, by March 1st.

TORONTO.—*Commercial Intelligence* states that the municipality will shortly invite tenders for the supply of underground cables required in connection with the new power plant.

WORTHING.—An application is to be made for sanction to borrow £3,900 for electrical extensions.

Miscellaneous

BRIGHTON.—The Tramways Committee invite tenders for the supply of general stores during the year ended March 31st, 1910. Particulars from the engineer and manager, and tenders by February 20th.

CARDIFF.—The Corporation has sanctioned the expenditure of £11,175 upon track renewals and repairs.

LEEDS.—Tenders are invited for the supply of stores for the tramways department. Particulars from the General Manager, and tenders by February 20th.

MANCHESTER.—Tenders are invited by the Tramways Committee for the supply of general stores. Particulars from the General Manager, and tenders by February 23rd.

URUGUAY.—The *Review of the River Plate* states that Mr. A. R. Bennett, who was engaged by the Uruguayan Government to prepare a project for the installation of a national telephone service, has completed his report. It is stated that the Government has the intention of putting the work in hand at once.

WOLVERHAMPTON.—Tenders are invited by the Tramways Committee for 250 tons of 90 lb. steel rails, in addition to loops, cross-nuts, points, &c. Particulars from the Borough Engineer, and tenders by February 22nd.

YORK.—The Guardians of the York Union invite tenders for a system of telephones and fire-alarms. Tenders from the Clerk, 1 Museum Street, York, and tenders by February 24th.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—School, Buxton St., Whitechapel. (£11,723.) Builders, C. P. Roberts & Co., 138 St. Paul's Road, Highbury.

N.E.—School, Greenleaf Rd., Walthamstow. (£11,550.) H. Prosser, Architect to the Committee.

W.C.—Addition to Savoy Hotel, Strand. Architects, Callcutt & Hamp, 36 Bloomsbury Sq., W.C.

LONDON COUNTY COUNCIL.—The Council invite tenders for the electric lighting, bells, and fans at the Queen's Square School, Bloomsbury. Particulars from the Engineer, and tenders by February 24th.

The Hampstead Guardians are to obtain estimates for installing electric light in the workhouse mortuary where oil-lamps have hitherto been used.

PROVINCES.

BLACKPOOL.—Free Library. Architects, Cullen, Lockhead & Brown Hamilton (Glasgow).

BOGNOR.—Isolation Hospital. O. A. Bridges, Surveyor to U.D.C.

BRISTOL.—Alterations and additions to Infirmary. H. Percy Adams, 28 Woburn Place, W.C.

BUXTON.—Church. Architect, C. Swan, College Rd., Buxton.

CHESHIRE.—Additions Agricultural College. Architect, H. Beswick, Newgate St., Chester.

COVENTRY.—Two Elementary Schools. (£27,500.) F. G. Boon, Surveyor, Coventry Town Council.

DARLINGTON.—Secondary School. Architect, F. Rushworth, Shire Hall, Durham.

DUDLEY.—Enlargement of Post Office. (£7,146.) Builder, John Barnsley & Sons, 102 Ryland St., Birmingham.

DUNFERMLINE.—Gymnasium. (£5,000.) Architect, H. D. Barclay, 245 St. Vincent St., Glasgow.

DURHAM.—Additions Technical School. (£5,000.) Architects, Oliver, Leeson & Wood, Milburn House, Newcastle-on-Tyne.

EDINBURGH.—Police Station, McLeod St. City Architect, Edinburgh.

GREENOCK.—Roman Catholic School, Patrick St. Architect, W. R. Watson, 95 Bath St., Glasgow.

HALIFAX.—Tenders are invited for the wiring of new bank premises in Halifax. Architects, Messrs. R. Horsfall & Son, 22a Commercial Street, Halifax.

KENT.—County school for girls at Dartford; additions to county school at Sittingbourne (£400); additions to grammar school for boys at Maidstone (£600); elementary schools at Denton, Edenbridge, Sheerness, and Sittingbourne. Architect, W. H. Robinson, Council Offices, Caxton House, Westminster, S.W.

MANCHESTER.—Library. T. de Courcy Meade, Surveyor, Manchester Town Council.

MERTON.—Horticultural College (£200,000). Trustees under the will of the late Mr. John Innes (Charles Clare Scott, Frederick George Courthope, William Ernest Reid Innes, and others to be appointed).

NOTTINGHAM.—Mechanics' institution. Architect, W. B. Starr, 12 St. Peter's Gate, Nottingham.

WOLVERHAMPTON.—Swimming baths (£6,000). G. Green, Borough Surveyor.

County school (£20,000). Architect, F. Fleeming, Midland Bank Chambers, Wolverhampton.

L.C.C. Tramways Assessment.—In the King's Bench Division of the High Court last week a decision was given in the dispute between the London County Council and the Income Tax Commissioners. It appears that, prior to electrification, an arrangement between the parties was in force under which an allowance was made, before assessment, on the basis of the actual expenditure upon renewals, instead of upon an estimate of the wear and tear. The dispute was in respect of the year 1904, when conversion to electric traction in South London took place, and the Council claimed that an allowance should be made for the worn-out lines which had been replaced by lines suitable for electric traction. It was also claimed that some allowance should be made for wear and tear of cars. The Income Tax Commissioners, however, argued that the reconstruction of electric traction did not constitute renewals, and the Court upheld this view.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

BRADFORD.—The Electricity Committee recommend the acceptance of a tender of the British Thomson-Houston Co. for two turbines and alternators.

GLASGOW.—The Tramways Committee have accepted the offer of the National Conduit & Cable Co., Ltd., for lead-covered cables. The tender of this firm was the lowest received.

GREAT NORTHERN & CITY RAILWAY CO.—Messrs. Siemens Bros. Dynamo Works, Ltd., 6 Bath Street, City Road, have secured the contract for the supply of tantalum traction lamps.

LONDON: *Metropolitan Asylums Board.*—An agreement has been entered into with the Electrical Power Storage Co., Ltd., to maintain the storage battery on the training ship *Exmouth* for five years at £8 per annum.

London County Council.—For the purpose of the private telephone service in the tramways department, the Highways Committee reports that it is necessary to provide instruments at the car-sheds at Stamford Hill, Holloway, Poplar, Bow, Hackney, Hammersmith, and Norwood. The installation of these instruments will allow of the removal of those at present in these buildings which belong to the National Telephone Co., and the arrangement will result in a saving of £87 1s. a year. The Council on March 31st, 1908, decided to accept the tender of W. T. Henley's Telegraph Works Co., Ltd., amounting to £35.101 4s. 7d., for the supply of low-tension electric cables and telephone cables, and it is recommended that extra work should be carried out as an extension of their existing contract. The estimated cost of the instruments required, together with the necessary wiring, will amount to about £160.

Woolwich.—An order has been placed with the General Electric Co., Ltd., for 1,000 "Osram" lamps of various kinds, to be delivered in quantities as required during the next twelve months.

MAIDSTONE.—An order has been placed with Messrs. Drake & Gorham for a switchboard at £53 11s.

SOUTHAMPTON.—The Town Council have accepted the tender of Walter Scott, Ltd., for a supply of tramway rails.

WEST HAM.—The tender of the British Electric Transformer Co. for two 400-kw. transformers to transform from 2,300 to 5,000 volts has been provisionally accepted, and that of the same company for two 250-kw. single phase transformers at £184 each.

Electric Pressure-testing Stations in London.—The London County Council some time ago decided to require the Kensington and Knightsbridge and the Brompton and Kensington Electric Lighting Companies, the County of London Electric Supply Company, the St. Marylebone and Islington Metropolitan Borough Councils, and the South London Electric Supply Corporation, Limited, respectfully, to provide and maintain testing stations in accordance with the provisions of their Orders. Subsequently the Council approved a scale of charges to be paid in respect of services rendered by the Council's inspectors in connection with such stations. Later a deputation of authorities waited on the Council, and urged that the establishment of testing stations was at the present time unnecessary, and, therefore, wasteful, having regard to the fact that a sufficient test could be made on the premises of any consumer. The deputation, however, stated that they thought the borough councils affected would be prepared to agree to tests being carried out generally on the basis outlined below: (1) The borough councils to afford facilities for the Council's tests to be made at generating stations, sub-stations, or other places in each borough to be agreed between the Council's officers and the officers of the authorities concerned, the recording voltmeters to be sealed during the tests, and the Council's officers to break the seal, and bring away the records to the County Hall. (2) Each borough council to grant facilities for special tests at any point desired by the Council. (3) The borough councils to provide at their own cost all recording voltmeters and other instruments required for the tests above referred to, such instruments to be approved and certified by the Board of Trade. The Highways Committee agree to this, and recommend that generating stations and sub-stations with "pilot" wires run back from distant points be in approved cases accepted as testing stations within the meaning of the electric lighting Acts and Orders subject to the conditions—that conclusive proof is afforded that such "pilot wires" are properly connected at the distant parts of the system indicated; that connections are made, as far as possible, at such points as may be indicated on behalf of the Council by the chief engineer, suitable instruments being placed solely at the disposal of the electric inspectors making the tests and the instruments sealed by the inspectors; and that where "pilot wires" are used, the supply undertakers shall be required to make such further tests on the premises of any consumer as the inspector may require, and provide the necessary apparatus and connections at their own expense.

MISCELLANEOUS CITY NOTES

LANARKSHIRE TRAMWAYS CO.—An issue of 3,500 £10 shares is being made to meet the cost of extensions.

BRITISH ELECTRIC TRACTION CO.—A dividend of 1½ per cent. (3s. per share), less tax, is announced upon the preference shares.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—We are asked to state that the transfer books and register of members of this company will be closed from February 18th to March 1st (both days inclusive).

W. T. HENLEY'S TELEGRAPH WORKS CO., LTD.—A dividend of 15 per cent., free of income tax, including the interim dividend of 5 per cent. paid in September, is recommended for the year 1908.

CHELSEA ELECTRICITY SUPPLY CO.—The directors recommend the full dividend for the half-year to December 31st upon the 6 per cent. preference shares, and 5 per cent. per annum upon the ordinary shares. After placing certain sums to depreciation, debenture premium, redemption fund, and cost of extinction of founders' shares, the sum of £1,024 is carried forward against £904 last year.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS.—An issue of an additional 65,000 £1 shares has been announced.

Fire on the Lancashire & Yorkshire Railway.—Another fire occurred on a train on the Liverpool and Southport Electric Railway on Saturday last. Smoke was observed to be issuing from a carriage of a train when running between Freshfield and Formby stations, but the train was stopped and the fire extinguished before much damage had been done. The outbreak is stated in the Press to have been due to a short circuit.

Telegraphic Traffic.—The lines of the Indo-European Telegraph Co. were interrupted on the 10th inst. between Tiflis and Tauris, but were restored to working order on the 11th inst. On the former date communication between Bagdad and Bassorah and *vid* El Arich, Hanekin, and Konia, was again in normal condition. An interruption, however, occurred again on the 11th inst. On the 13th telegraphic communication by the Malta-Italy route was no longer subject to delay.

Obituary.—We regret to announce the death, at the age of 71, of Mr. G. E. Belliss, of the well-known firm of engine builders, Messrs. Belliss & Morcom, Ltd. The business was founded by Mr. Belliss as far back as 1862, but it was not until 1869 that the manufacture of engines was introduced, when Mr. Belliss was joined by Mr. A. Morcom, who had been the Admiralty's Chief Engineer at Sheerness Docks.

Wireless Telegraphy and Telephony.—The inhabitants of North Ronaldshay, the most northern of the Orkney Islands, have asked for an extension of the telegraph service across the firth between Sanday Island and their own island. As the strong currents and the nature of the sea bottom between the islands would necessitate an expensive cable, experiments are being carried out with the idea of establishing a wireless service.

A wireless station was opened to the public in Copenhagen on February 1st, and is available for the interchange of messages with vessels at sea up to a distance of 300 kilometres. All Danish telegraph offices now accept messages for transmission by wireless telegraphy.

The Admiralty have decided to form a reserve of wireless telegraph operators. Telegraphist ratings, on leaving the service, can enrol in the Royal Fleet Reserve, on condition that they continue as wireless telegraph operators in civil life.

Dr. Lee de Forest has publicly announced that he has succeeded in obtaining excellent results with a new system of wireless telephony, which is to be used in installations along the Atlantic coast. On the other hand, it is reported from Washington that most unsatisfactory results have been obtained with the wireless telephone apparatus installed on board the vessels of the American fleet, and that in all probability the apparatus will be removed.

Marconi's Wireless Telegraph Co., Ltd., have received orders from the Norddeutscher Lloyd Shipping Co. to equip the following nine steamers with wireless apparatus:—*König Albert, Friedrich der Grosse, Prinzessin Alice, Barbarossa, Königin Luise, Prinzessin Irene, Rhein, Main, and Neckar.*

Judgment was given yesterday in an action brought by the Maatschappij Voor Radiotelegraphic against the Marconi Wireless Telegraph Co., Ltd., with regard to three bills of exchange for £300 each, which had been dishonoured on presentation. The dispute arose with regard to an agreement between the two companies which had been accepted on behalf of the English company by Mr. Cuthbert Hall, formerly managing director of the company, but whose action in the matter the Marconi Co. now wished to repudiate. Judgment was given, however, in favour of the Dutch company.

Mr. J. R. Binns, the wireless telegraph operator of the *Republic*, who communicated the news of the collision with the *Florida* to vessels near by, and obtained assistance, was presented with a gold watch by the directors of Marconi's Wireless Telegraph Co., Ltd., last week.

COMPANIES' MEETINGS AND REPORTS

BAKER STREET & WATERLOO RAILWAY CO.—The accounts for the half-year ended December 31st, 1908, state that the revenue of the company continues to increase satisfactorily. The gross receipts amounted to £86,355, being an increase of £17,106, or 24·70 per cent., on the receipts for the corresponding half of 1907. The working expenses amounted to £44,663, being an increase of £737, or 1·68 per cent. After providing for interest and rents, and for dividend at the rate of 4 per cent. per annum on the preference shares, there remains a balance of £12,081 available for dividend on the ordinary shares, and the directors recommend that a dividend at the rate of ¾ per cent. per annum be declared on the ordinary shares, and an additional dividend at the rate of 2¼ per cent. per annum (making 3 per cent. per annum in all) on the ordinary shares other than those held by the Underground Company or their nominees, leaving a balance of £2,247 to be carried to next half-year. The number of passengers carried was 13,337,126, compared with 10,662,876 in the corresponding period of last year; the average receipt per passenger was 1·48d., compared with 1·50d.; and the train mileage was 594,381, compared with 523,239. A Bill is being promoted in Parliament, which will be submitted to the proprietors for approval at the special meeting to be held after the conclusion of the ordinary meeting on the 18th inst., seeking powers to extend for two years from August 4th, 1911, the time for constructing the authorised extension to Paddington, and to purchase certain property adjoining Oxford Circus Station for the purpose of enlarging that station in order to provide more accommodation for the increasing traffic. The Bill also seeks power to abandon certain authorised subway works under Trafalgar Square. A Bill has been deposited in Parliament by the North-West London Railway Company seeking power to abandon the portion of their authorised railway between Edgware Road and Victoria, and to join their authorised line from Brondesbury to Edgware Road with this company's railway at Edgware Road Station, so that the two railways may be worked as one continuous line. An agreement providing for the management, maintenance, and working by this company of the North-West London Railway, when constructed by the North-West London Company between Edgware Road and Brondesbury, is under negotiation, and, if terms are arranged, will be submitted to the proprietors for approval at a special meeting to be summoned for the purpose.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO.—The accounts for the year ended December 31st, 1908, state that the gross earnings of the West End undertakings were £139,253 as compared with £131,920 in 1907, and the expenses, including depreciation, were £87,785 against £80,114. After bringing in the balance of £4,023 from 1907, and £5,502 for interest accrued in 1908, and paying interest on the debenture stock, there is a balance on net revenue account of £43,163, out of which have been paid the dividend for the year on the preference shares, and an interim dividend for the first half-year at the rate of 5 per cent. per annum on the ordinary shares, leaving a balance to be dealt with of £15,163. The directors recommend a final dividend on the ordinary shares for the second half-year at the rate of £5 per cent. per annum, making £5 per cent. for the whole year, carrying forward the balance of £5,163, as against the £4,023 last year. The company has now connected to its West End mains a total equivalent of 579,492 8-c.p. (or 30-watt) lamps, or an increase of 40,528 as against 28,375 added last year. The total is made up as follows: 412,900 in lighting, 13,317 in heating, and 153,275 (6,131 h.p.—4,574 kw.) in motive power. In addition, a bulk supply is being furnished to the London County Council at their station on the Victoria Embankment. The gross earnings of the City undertaking were £131,012 as compared with £118,543 in 1907, and the expenses £76,561 against £63,748. After bringing in the balance of £2,256 from 1907, and paying interest on the debenture bonds, debenture stock, and temporary loans, there is shown a balance on net revenue account of £23,110, out of which has been paid the dividend on the preference shares amounting to £18,000, leaving to carry forward £5,110 as against £2,256 last year. The 5 per cent. debenture bonds of the City undertaking matured on January 15th last and have been redeemed. The company has now connected to its City mains the total equivalent of 494,783—8 c.p. (or 30-watt) lamps, which is an increase of 40,026 upon last year's figures. The total includes 295,201 in lighting, 30,057 in heating, and 169,525 (6,781 h.p.—5,058 kw.) in motive power. The company are also furnishing a bulk supply to the Smithfield Market Electric Supply Co., Ltd. A short *résumé* of the London Electric Supply Act, 1908, is given at the end of the report. The meeting is to-day.

MATHER & PLATT.—The report for the year 1908 shows net profits, including the balance brought forward, of £155,512 after providing for depreciation and directors' fees. The sum of £35,000 is transferred to reserve, making this fund £375,000, and £30,512 are carried forward. A dividend of 10 per cent. per annum on the ordinary shares, less the interim dividend paid in September, a bonus of 7½ per cent., is recommended.

CITY OF BUENOS AYRES TRAMWAYS CO. (1904).—The report for the year ending December 31st, 1908, states that the annuity payable by the Anglo-Argentine Tramways Company has been received, and the net revenue for the year amounted to £65,448. Interim dividends have been paid for the nine months ending September 30th, 1908, absorbing £46,500, leaving a balance of £18,948 9s. The directors recommend that this balance be disposed of as follows:—Final dividend of 1s. 3d. per share (making 5s. per share, less income tax) be paid for the year ending December 31st, 1908, absorbing £15,500; that the sum of £3,500 be transferred to general amortisation fund, and that the balance of £148 9s. be carried forward. The amortisation fund for the debenture capital, with accrued interest to date, amounts to the sum of £13,167 5s. 4d. The general amortisation fund for the redemption of the share capital now amounts to £21,296, included therein being a further sum of £93, the proceeds of sale during the year of a small strip of land in Buenos Ayres for railway development. At the meeting on Monday the report and accounts were adopted.

ST. JAMES'S & PALL MALL ELECTRIC LIGHT CO.—The report for 1908 states that the supply distributed from the Carnaby Street and Mason's Yard Works has been 11,729 kilowatts, an increase of 803 kilowatts. For this purpose 4,968,280 units were generated at the company's works, and 6,370,250 units were purchased from the Central Electric Supply Co., Ltd. The report and accounts for the past year of the Central Electric Supply Co., Ltd., show that a dividend of 5 per cent. on the ordinary shares has been declared, in respect of which a sum of £2,500 will in due course be payable to the company. The directors have raised the contingency fund to the sum of £5,000 by transferring from the net revenue of the past year an amount of £3,500. The net profits for the year 1908 amount to £29,330, and adding the balance brought forward from 1907, viz., £1,375, there is a balance available of £30,705. Interim dividends paid in August last for half-year ending June 30th absorbed £13,500, leaving an amount now to be dealt with of £17,205. The 7 per cent. dividend on the preference shares for the second half-year absorbs £3,500; a dividend on the ordinary shares for the second half-year of 5s. per share, making, with the interim dividend paid in August last, a total distribution of 10 per cent. for the year, £10,000, leaving £3,705 to be carried forward. In March last Colonel Eustace Balfour retired from the chair, and Mr. Walter Leaf was unanimously chosen to take this position. The Chairman, Mr. Walter Leaf, and Colonel Eustace Balfour are the directors who retire by rotation, and, being eligible, offer themselves for re-election. At the meeting on Tuesday the report and accounts were adoptd.

CENTRAL ELECTRIC SUPPLY CO.—The report for 1908 states that energy has been supplied to the St. James's and Pall Mall Electric Light Company, Limited, and the Westminster Electric Supply Corporation, Limited, throughout the year to an amount of 18,859,180 units. After making a full allowance for sinking fund and depreciation, the net balance for the year 1908 is £5,023, including balance brought forward from last year. The directors now propose a dividend at the rate of 5 per cent. on the ordinary shares for the year, carrying forward £23 10s.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY CO.—At a meeting last week a resolution was passed confirming the Bill which has been deposited in Parliament for extending the "special districts" in which the company may be allowed to supply electricity for power and lighting purposes so as to include Hendon, Finchley, Friern Barnet, Hornsey, Walthamstow, Chingford, and Waltham Cross. Permission is also asked to raise any part of the unissued capital (approximately £100,000), and to increase the nominal capital by £250,000.

YORKSHIRE ELECTRIC POWER CO.—The report for the twelve months ended December 31st, 1908, states that the total receipts were £18,643 against £11,994 for the year 1907, the gross profit was £2,819 against £433 for the year 1907. After payment of mortgage interest there is a balance of £717 against a loss of £1,350 for the year 1907. Notwithstanding the general slackness in all the industries of the districts, there has been steady and continuous growth in the business of the Power Co. At December 31st, 1908, agreements with consumers had been made for a total demand of 8,333 kw. (11,170 h.p.), an increase over those of 1907 of 2,785 kw. and 3,733 (equivalent h.p.). The supply of energy for tramway purposes in Ossett and Soothill Nether was commenced in November last. The new overhead mains passing through Thornhill, Whitley Upper, Flockton, Emley, Skelmanthorpe, and Clayton West, in the direction of Barnsley, have been erected, and a supply of electrical energy has just been commenced from these mains. A number of important agreements with colliery proprietors and other power users in the districts through which the mains run have been concluded, and it is anticipated that a large and growing load will be secured on this route. The directors have pleasure in reporting a continuous increase in the requirements of textile factories, which class of consumer has been during the past year the most important user of the company's supply. In addition to new customers secured over the whole area supplied by the company, the directors again note the steady growth of demand from existing consumers who constantly extend the use of the company's power in their works, thus proving in the most emphatic way their appreciation of the advantages obtained. The increasing demands have necessitated the installation of an additional boiler at Thornhill. This is in course of erection, and will be handed over to the company in a few weeks. In spite of the high price

Digitized by Google

of coal during the past year the increased output of current has again reduced the average cost per unit sold. Of the issue of £45,000 of second mortgages on the undertaking of the company, £33,205 have been applied for and allotted up to December 31st last.

IMPERIAL TRAMWAYS CO.—The report for the year to December 31st, gives the following information :—*Middlesbrough, Stockton, and Thornaby Electric Tramways.*—The gross receipts from this undertaking amounted to £50,905, as compared with £54,747 for the previous year. The number of passengers carried was 10,014,056, against 10,700,643 last year. After placing £1,100 to the reserve fund for renewals (bringing the total of that fund up to £17,000), the net profit for the year is £16,871, as compared with £16,884 8s. 10d. for the corresponding period. The falling off in the traffic receipts for the year is wholly attributable to the unsettled trade conditions and lack of employment in the engineering and shipbuilding trades of the district served by the company's system. *London United Tramways.*—The company's investment in this undertaking remains at 44,446 five per cent. cumulative preference fully-paid shares of £10 each. The full dividend of 5 per cent per annum was received on these shares for the first half of the year, but for the second half-year only 2½ per cent per annum was paid on account. The directors of the London United Co. state that, although the revenue account for the year will doubtless show a balance sufficient to cover the full dividend on the preference shares, they have adopted the policy of reducing the preference dividend for the present, with a view to strengthening the reserve funds. The directors were much disappointed to receive an intimation of this nature, having regarded the Imperial Co.'s income from the investment in London United Tramways preference shares as a fully assured one, and they yet trust the developments in connection with the London United undertaking will enable the directors of that company to make up the arrears and resume payment of the full rate of 5 per cent. on the cumulative preference shares at no distant date. *General.*—The effect of the non-receipt of the full rate of dividend from the London United Tramways investment is that the Imperial Co.'s revenue account is depleted by the sum of £5,278, representing between 5 and 6 per cent. per annum for the half-year on the Imperial ordinary capital. In the result, therefore, the net revenue account for the year shows an available balance of £35,943 4s. 8d. only, and after payment of interest on the debenture stock for the whole year, and interim dividends on the preference and ordinary shares in respect of the half-year to June 30th last, amounting together to £26,125, it is proposed to appropriate the balance as follows :—6 per cent. dividend on the preference capital (paid on January 1st last) £5,700, final dividend at 4 per cent. per annum (making 6 per cent. for the year) on the ordinary capital (less income tax) £3,800, and to carry forward to the next account £318 4s. 8d. The amount transferred from the ordinary shares dividend fund is £3,250, as compared with £3,750 in the preceding year.

At the meeting last week the report and accounts were adopted.

METROPOLITAN DISTRICT RAILWAY CO.—The report for the half-year ending December 31st, 1908, shows that the capital expenditure during the half-year has been £76,924, but after deducting £130,000 received from sale of cars to the London, Tilbury and Southend Railway Company, there is a net credit to capital account of £53,076. The company's revenue in the past half-year has increased in a most satisfactory manner, and the increases have occurred practically throughout the entire system. It is estimated that the additional revenue directly attributable to the Franco-British Exhibition has been about £10,000. The total number of passengers carried during the half-year was 31,503,722, compared with 25,808,732 in the corresponding period of 1907. The gross receipts amount to £261,874, being an increase of £37,411 on the receipts for the corresponding half of 1907. The working expenses amount to £153,868, being a decrease of £2,201. After providing for interest and other charges, the net revenue account shows a credit balance of £11,613, and the directors recommend that a dividend at the rate of £1 15s. per cent. per annum be declared on the 4 per cent. guaranteed stock payable on February 12th. During the half-year £550,000 of the authorised prior lien debenture stock has been issued on satisfactory terms, and, out of the proceeds, the whole of the temporary loans on the security of the company's surplus lands have been paid off. The prior lien debenture stock was issued as redeemable at any time after December 31st, 1920, at the price of £105 for every £100 of stock. At the time when the railway was equipped for electric working, this company provided the whole of the rolling stock required for working, not only their own railway, but also the Whitechapel and Bow Railway, and a portion of the London, Tilbury and Southend Railway. In the directors' report of February last it was stated that terms for the use of the District cars on the Tilbury Railway had been settled with the Tilbury Company for a period of five years. Since then, further negotiations have taken place, and the Tilbury Company have recognised the fairness of their bearing part of the capital expenditure involved in the provision of rolling stock. They have purchased thirty-seven motor cars and thirty-seven trailer cars for a sum practically equivalent to cost price. The amount received from the Tilbury Company for the cars so purchased, viz., £130,000, had been credited to capital as mentioned above. The sale of cars to the Tilbury Company having been arranged since the estimate of capital requirements was prepared for the purpose of fixing the amount to be raised by the issue of prior lien debenture stock, the directors consider that, in the altered circumstances, they ought not to issue £130,000 of the unissued balance of £200,000 prior lien debenture stock under the powers of the Act of 1908, without the consent of a majority of the holders of the debenture stock at a meeting of such holders, and if it should hereafter become necessary to raise moneys for capital expenditure by the issue of the above-mentioned amount of £130,000 prior lien debenture stock, such consent will be sought before the issue is made. The directors recommend that Mr. William Corwin Burton be elected a director of the company to fill the vacancy on the Board. The directors retiring by rotation are Mr. Murray Griffith, Mr. Ernest Law, and Sir Clifton Robinson, and, being eligible, they offer themselves for re-election.

At the half-yearly meeting on Thursday the report and accounts were adopted. Sir George Gibb, who presided, said that the receipts from passenger traffic were the highest that the company has ever had. In their endeavours to improve the traffic by improving the train service, he pointed out that during the last half-year the train mileage showed an increase of 24·12 per cent., a course of action which had been justified by the fact that the receipts per car mile were 9·52 compared with 9·45 for the previous half-year. There had also been a reduction in the cost of electrical energy from Lots Road, which had improved the financial position.

BRISTOL TRAMWAYS & CARRIAGE CO.—At the ordinary general meeting on Thursday the report and accounts given in our issue for February 4th were adopted. Sir George White, who presided, said, although it might be unpleasant for the shareholders to have to accept a lower dividend, owing to the decrease in receipts, he anticipated with perfect confidence that they would support the view that this was the sound and proper course to take.

LIVERPOOL OVERHEAD RAILWAY CO.—At the half-yearly meeting last week the report and accounts given in our issue for February 4th were adopted. Sir W. B. Forwood, who presided, said he regretted the unsatisfactory nature of the report, which was attributable to the general paralysis of trade in Liverpool, which had been more pronounced there than in any of the other principal towns in the United Kingdom. The municipal tramway system had also taken a large amount of the traffic from the railway. The directors were, therefore, actively engaged in trying to effect small economies which they hoped would in the aggregate bring about a reduction in the working expenses. They had saved £1,800 per annum in rates by an appeal against their assessment and by increasing their service to one of five minutes and decreasing their speed they were saving £1,200 per annum in their coal bill and stores. Most of these economies would not be fully felt until the current half-year.

TYNESIDE TRAMWAYS & TRAMROADS CO.—At the half-yearly meeting in Newcastle last week the report and accounts given in our last issue were adopted. Dr. J. T. Merz, the Chairman, who presided, said that the causes of the reduction in receipts during last year were well known, but he could say that at the end of the year the traffic receipts again came up to the level of those of the year before, and at the present time their receipts were much better than they were last year.

Institution of Electrical Engineers.—The following is the result of the ballot for new members on Thursday :—*Members :* Dr. Max Kloss, C. S. Schultz. *Associate Members :* G. J. L. Brown, H. N. Calvert, J. R. W. Grainge, A. S. Hawkins, E. J. Lincoln, H. W. Moore, J. H. Murray, A. D. Phillips, F. D. Pyne, E. E. Shatford, W. Smith, C. R. Sprague, T. G. Wright. *Associates :* J. S. Green, H. J. Simpson.

Central Technical College Old Students' Association.—All old students who have not yet notified their intention of attending the annual dinner, which will be held at the Trocadero on Saturday, should communicate with Mr. E. Wheeler, the Dinner Secretary, Central Technical College, South Kensington, S.W., immediately.

Bank Overdrafts at West Ham.—A motion was heard before Mr. Justice Neville in the Chancery Division on Tuesday, at the instance of the Attorney-General, to restrain the West Ham Corporation from enforcing the payment of a rate made for the purpose of paying off a bank overdraft of £20,000, as portion of an overdraft of about £90,000 on capital account, in respect of their electric lighting undertaking at March 31st, 1908. It was argued that, although under the Electric Lighting Acts any deficit on municipal electric lighting undertakings might be charged upon the rates, in this particular case the sum in respect of which the rate was being levied was a bank overdraft and illegal, inasmuch as it had not been sanctioned by the Local Government Board. The present motion was to prevent the enforcement of the rate in question until the trial of the action as to the legality of the procedure in levying the rate, and Mr. Justice Neville said that, having regard to the difficulty which would arise if he were to make an order on this motion, he thought the rate ought to wait until the trial.

APPOINTMENTS AND PERSONAL NOTES

Mr. R. Duncan, who has for a number of years been inspector of electric and hydraulic lifts and machinery generally to His Majesty's Postmaster-General, has been appointed London Manager to Messrs. A. and P. Steven, Thanet House, 231 Strand, London.

Mr. G. R. Askwith, K.C., at present Assistant Secretary in the Railway Department of the Board of Trade, has been appointed Comptroller-General of the Commercial, Labour, and Statistical Departments of the Board of Trade, in succession to Mr. A. Wilson Fox, C.B. Mr. W. F. Marwood, Principal Clerk in the Railway Department, succeeds Mr. Askwith as Assistant Secretary. A short while ago it was announced that Mr. Askwith was to succeed Sir C. N. Dalton as Comptroller of Patents.

Mr. W. Temple Franks has been appointed Comptroller-General of Patents, Trade Marks, and Designs, in succession to Sir C. N. Dalton.

An assistant, with technical and commercial experience, is required in the sales department of a firm of arc lamp makers. (See an advertisement.)

For the appointment of tramway inspector the Doncaster Corporation received 243 applications. A sub-committee has been formed to go through the list.

Mr. H. B. Harvey, who has been manager and engineer to the Cambridge Electric Supply Co. since 1901, has resigned his appointment in order to take up the position of manager and engineer to the Kent Power Co.

The salary of Mr. H. D. Munro, City Electrical Engineer at Exeter, has been increased by £25.

Mr. David Fulton, Electrical Engineer to the South Durham Iron & Steel Co., has received the appointment of Electrical Engineer to the Swansea Harbour Trust.

An accountant-clerk is required by the Institution of Electrical Engineers, at a salary of £200 per annum. (See advertisement this week.)

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f., port of arrival, quoted on Tuesday night, was £61 to £61 10s. per ton (£61 10s. to £62 last week).

AGENCIES.—We hear from Messrs. Gillespie and Beales, of Amberley House, Norfolk Street, Strand, London, that they have appointed Mr. James Turnbull, whose address is 3 New Street, Birmingham, as their representative and correspondent in the Birmingham district.

Messrs. Gillespie and Beales also advise us that they have been appointed agents for Messrs. William Rickard, Ltd., Derby, makers of vulcanised india-rubber and other wires and cables.

The Midland Electric Manufacturing Co., Ltd., have appointed as their sole London representative Messrs. Hogan & Wardrop, Gloucester Mansions, Charing Cross Road, London, W.C.

Messrs. Mawdsley's, Ltd., Zone Works, Dursley, Glos., have appointed Messrs. Paterson & Service, 38 Bath Street, Glasgow, as their representatives for Scotland, and Messrs. The Robinson & Hands Electrical Co., Ltd., 54 Barwick Street, Birmingham, as their representatives for the Birmingham district.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—The first meeting of creditors in the bankruptcy of Robert Russell, electrical engineer, The Garage, Dryad Street, Putney, was held last week. The statement of affairs showed gross liabilities of £834 14s. 9d., of which £747 14s. 9d. were expected to rank. The debtor has been in business about eleven years as an electrical engineer, and attributed his position to the loss of a legal action for misrepresentation and also to bad debts. The matter is left in the hands of the Official Receiver.

NEW WORKS.—Messrs. Mountain & Gibson, Ltd., of Bury, having acquired the firm of Messrs. Thornewill & Warham, Iron Founders, of Burton, are about to open new works in Burton-on-Trent.

NEW COMPANIES

IMPERIAL LAMP WORKS (BRIMSDOWN).—This company was registered on January 27th, with a capital of £1,000 in 5s. shares, to take over the business of manufacturers of and dealers in electrical lamps and fittings, carried on at the Imperial Works, Brimsdown, Middlesex, and to adopt an agreement with A. A. Flurscheim (trading as the Power Plant Construction Co.). Private company. The number of directors is not to be less than two nor more than five; the subscribers are to appoint the first. Qualification, 100 shares. Remuneration as fixed by the company. Registered by J. R. Cardew-Smith, 13 Bedford Row, W.C.

POPE'S ELECTRIC LAMP CO.—This company was registered on January 26th, with capital of £25,100 in £1 shares (25,000 preference), to take over the business of electrical lamp manufacturers and merchants carried on by Emile Goossens, F. R. Pope, and M. W. O'Connell, as "Pope Electric Lamp Co.," at 9 Hythe Road, Willesden. The subscribers are:—M. W. O'Connell, 35 Nicoll Road, Harlesden, N.W., electrical engineer; F. R. Pope, The Priory, Harlesden Road, N.W., electrical engineer. Private company. The first directors are F. R. Pope, M. W. O'Connell, and E. Goossens. Qualification, £1,000. Remuneration of F. R. Pope, M. W. O'Connell, and E. Goossens, £250, £250, and £125 per annum respectively. Registered by W. H. Martin and Co., 15 King Street, E.C. Registered office, 9 Hythe Road, Willesden, N.W.

C. SHARDLOW & CO.—This company was registered on February 2nd, with a capital of £2,000 in £1 shares (1,500 pref.), to acquire the business carried on by C. Shardlow, as "Shardlow & Co.," and to carry on the business of mechanical and electrical engineers, suppliers of electricity, founders, millwrights, hardware and plumbers' merchants, steam, water and gas-fitters, &c. Private company. The number of directors is not to be more than five. C. Shardlow is the first managing director and chairman. Qualification of first director, 300 ordinary shares; of subsequent directors, 100 shares. Remuneration of C. Shardlow, £220 per annum. Registered office: Britannia Foundry, St. Peter's Lane, Leicester.

LONDON ELECTRIC WIRE CO. & SMITHS, LTD.—This company was registered on January 30th, with a capital of £420,000 in £5 shares (14,000 pref.), to acquire (1) the undertaking of the London Electric Wire Co., Ltd., together with shares in that company, and (2) the Salford undertaking of Frederick Smith & Co., Wire Manufacturers, Ltd., to adopt agreements (1) with the London Electric Wire Co., Ltd., and W. H. Willey, the liquidator thereof, and (2) with F. Smith (on behalf of Frederick Smith & Co., Wire Manufacturers, Ltd.), and to carry on the business of wire manufacturers and coverers, cable makers, electrical engineers, makers of machinery, tools, and appliances for telegraphs, telephones, and other electrical purposes, &c. The subscribers are:—T. Willey, M.D., Saxmundham House, Swanage; A. L. Don, 2 North Grove, Highgate, N., gent.; F. Leete, Trefusis, Kenley, Surrey, gent.; F. Smith, Dunham Lawn, Bowdon, Cheshire, electrical engineer; W. H. Willey, 7 Playhouse Yard, Golden Lane, E.C., electrical engineer; A. N. Smith, Anaconda Works, Salford, electrical engineer; W. C. Jackson, 58 Coleman Street, E.C., C.A. Minimum cash subscription, 7 shares. The number of directors is not to be less than three nor more than nine: the first are T. Willey, M.D., A. L. Don, F. Leete, F. Smith, W. H. Willey, and A. N. Smith. Qualification, 1 share. Remuneration, £200 each per annum (chairman, £250). Registered office: 7 Playhouse Yard, E.C.

STERLING TELEPHONE & ELECTRIC CO.—This company was registered on February 3rd, with a capital of £65,000 in £1 shares (49,650 6 per cent. cumulative participating pref. and 15,350 ordinary), to carry on the business of telephonic, electrical, and mechanical engineers, suppliers of telephonic apparatus, and of electricity for all purposes, &c. Private company. The number of directors is not to be less than two nor more than five. So long as the Telephon Fabrik Actien Gesellschaft *vormals* J. Berliner hold 10,500 shares, they may nominate two directors. Registered office: 200 Upper Thames Street, E.C.

ELECTRIC PULLEY-BLOCK CO.—Registered on February 5th, with a capital of £2,000 in £1 shares, to adopt an agreement with A. A. C. Gese, and to carry on the business of electrical and general engineers, founders, &c. The subscribers are:—A. A. C. Gese, Nordstrasse 63, Bremen, Germany, engineer; A. W. S. Pocklington, 109 Victoria Street, Westminster, electrical engineer; T. Petersen, Hamilton House, Victoria Embankment, E.C., engineer. Private company. The number of directors is not to be less than two nor more than five; the first are A. A C. Gese, A. W. S. Pocklington, and T. Petersen. Registered office: 109 Victoria Street, Westminster.

POWER INVESTMENT TRUST.—Registered on February 4th, with a capital of £30,000 in £1 shares (20,000 5 per cent. non-cumulative preference) to acquire from time to time shares, stocks, and securities from William P. Bonbright and Co., and to carry on the business of bankers, capitalists, financiers, concessionaires, merchants, directors in stocks, shares, debentures, debenture stock, and other securities, &c. Minimum cash subscription 10 per cent. of the shares offered to the public. The first directors (not less than three nor more than five) are R. N. Grenfell, L. Egerton, Lord Fairfax, and W. F. Fisher. In the event of either of the above directors ceasing to act before the general meeting in 1913, William P. Bonbright and Co. may appoint a successor. Qualifications, £100 ordinary shares. Remuneration, £100 per annum, dividend. Registered office: 15 George Street, E.C.

APPOINTMENT VACANT.

ACCOUNTANT-CLERK wanted to take charge of Accounts and to assist Secretary in general work of office. Salary, £200. Apply in writing, stating age and qualifications, to the Secretary, INSTITUTION OF ELECTRICAL ENGINEERS, 92, Victoria Street, London, S.W., on or before February 26th.

Digitized by Google

GAS ENGINES v. STEAM TURBINES

MESSRS. LEONARD ANDREWS and Reginald Porter have presented to the Institution of Electrical Engineers an interesting Paper on "The Use of Large Gas Engines for Generating Electric Power," which was discussed simultaneously in London and Dublin last Thursday, and was also discussed in Manchester last Tuesday. The discussion in London will be continued next Thursday.

The authors commenced by pointing out that the use of large gas engines has hitherto been chiefly confined to iron and steel works where blast furnaces and other waste gases are used for driving blowing engines and generating electric power, and they give credit to the German iron and steel industry for having created the demand which has brought the large gas engine to its present state of perfection. They next referred to the report presented by a special committee to the National Electric Light Association in Chicago last May, which included descriptions of some of the large American gas engines, and a number of tabulated replies to inquiries as to the output consumption, cost of repairs, &c. In the summary attached to this report, it is stated that the efficiency of the combined gas engine and producer is higher than that of the combined steam plant, and that there are at least 300,000 h.p. in large units installed or being built in the United States. Whilst the cost of gas engines is at present much in excess of that of steam engines of the same capacity, the committee believe that it would be possible to build a combined producer and gas-engine plant at a cost approximating to that of the combined boiler and steam-engine plant when all auxiliaries and buildings are included.

The authors, however, do not look so far into the future, and they take the position as being that the internal combustion

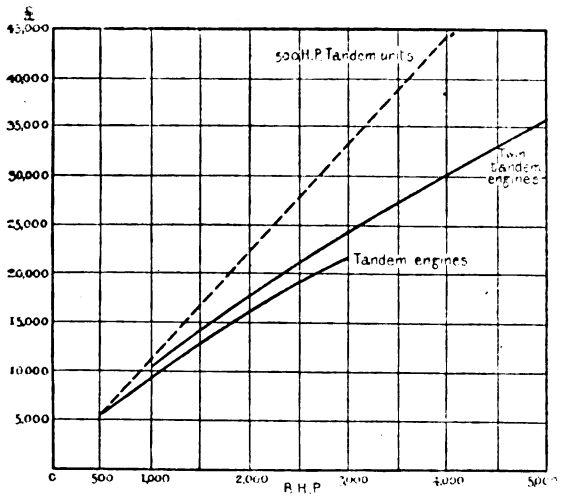

FIG. 1.—CAPITAL COSTS OF SLOW-SPEED HORIZONTAL GAS ENGINES.

engine is the more economical, but that the capital cost of the gas-engine and producer plant is greater than that of the equivalent steam turbine and boiler plant of equivalent overload capacity, and, finally, that there is no material difference in the reliability, or in the cost of labour, stores, or repairs of the two systems. Thus, when the cost of fuel is low and the load factor is low, it would generally be a mistake to use gas engines. On the other hand, with increasing load factor and increasing cost of fuel the authors contend that gas engines will prove to be the most economical.

In order to make an effective comparison, they take an actual case of plant to deal with a maximum load of 8,000 kw. with a load factor of 24 per cent., and a ratio of units sold to units generated of 80 per cent. They further assume that a good bituminous slack coal is used in both cases with a calorific value of 13,000 B.Th.U.'s per lb., and that it costs 12s. per ton delivered in the bunkers. This part of the Paper is interesting, not only for the actual comparison, but also for the method which the authors have employed for forecasting the costs of the steam-driven station.

It is impossible to estimate the cost of obtaining a site with a plentiful water supply, since this will vary largely in every case, and the authors have, therefore, based their comparisons upon the assumption that town's water will be employed and cooling towers. Drawings were exhibited, showing the lay-outs for the steam plant and gas plant upon which the estimates are based. For the steam plant horizontal steam turbines are taken, each exhausting into its own condenser beneath, and for the gas plant slow-speed four-cycle double-acting tandem engines directly coupled to overhanging fly-wheel generators. Three-phase alternators are assumed in both cases. For the maximum output of 8,000 kw., the authors assume the most economical arrangement in the steam-driven station to be five sets, each with a normal capacity of 2,000 kw. and an overload capacity of 33⅓ per cent. for two hours. This number of units is chosen for the reason that, in the event of two plants being laid off simultaneously, the remaining three sets would be capable of supplying the maximum demand for a period of two hours. In the gas scheme, however, the authors did not consider it advisable to use such large units as 2,000 kw., since the overload capacity of gas engines is only 10 per cent. or 12 per cent., and, consequently, they have taken 7 units, each with a normal capacity of 1,450 kw. and an overload capacity of 1,600 kw.

Fig. 1 shows the approximate capital cost of gas engines and generators, complete with pipework and foundations, and with the flywheels necessary to maintain the cyclic irregularity within 1/250. These curves show that the capital cost of a twin-tandem set is appreciably higher than that of a single-tandem set of the same output. The cost of fuel, oil, and repairs will be slightly higher for the twin-tandem combination, and the cost of driver's wages for the twin-tandem will be practically double. The authors have, therefore, chosen single-tandem engines for their scheme, but they point out that if larger sets could be used it might be more economical to employ twin-tandem machines.

In the case of the steam plant, they have taken four 10,000-lb. boilers for each 2,000-kw. turbine, these to be of water-tube type with self-contained superheaters and automatic stokers. An economiser is provided for each boiler. In order to keep the boiler-house about the same length as the engine-room, they have taken two rows of 10 boilers grouped in five batteries of four boilers.

From inquiries made, both in Germany and the United States, the authors have learned that large producers for utilising bituminous coal have not been entirely satisfactory. They suggest that the reason for this may be that the class of coal available in these countries contained a far greater percentage of ash and is much more liable to clinker than the bituminous coal here, for they state that there are numbers of bituminous-producer installations in this country working entirely satisfactorily in conjunction with large gas engines. One firm of English producer-makers alone have at the present time producer-plants in operation supplying gas to large engines with an aggregate capacity of over 90,000 b.h.p.

The question of ammonia-recovery plant is next dealt with. Experience up to the present has indicated that it is not worth while attempting to recover sulphate of ammonia unless the total output of the plant is greater than 2,000 h.p., and then only on an exceedingly good load factor. In their typical case of 8,000 kw. on a load factor of 24 per cent., the authors have taken it that there will be eight producers, of which four only are equipped for ammonia recovery.

In estimating the cost of the buildings, the authors have arrived at a lower cost for the gas plant than the steam plant; for, although the cost of the engine-room and engine foundations is much greater for the gas engine, no building is required for the producers beyond the small boiler and sulphate houses, and the cost of the foundations for the producers is very small compared with the cost of boiler foundations, flues, and chimneys.

In both the steam and gas plant it is assumed that two steam-driven exciter sets will be employed, supplemented by a battery capable of maintaining the full field current for 24 hours. In the gas station the steam for the exciter sets would be furnished from a small coal- or tar-fired boiler, and the exhaust steam from the exciter engines would be used in the producers, any additional steam required by the latter being raised by boilers heated by the exhaust gases from the main engine.

For generating stations built on this basis, the authors estimate as the cost of the steam station £139,525, or £13·952 per kw. installed, and for the gas station £176,875, or £17·68 per kw. installed. Neither of these figures includes the cost of land.

In considering the question of steam consumption, the authors exhibited the curve reproduced in Fig. 2. They have plotted it from a number of published tests of steam turbines and gas engines of different sizes. The ordinates above the zero line represent the steam and fuel utilised for the actual generation of electric power, and those below the zero indicate the fuel required per hour to run the generators at full E.M.F. on open

Digitized by Google

circuit. While the efficiency of the steam turbine depends on the size of the plant, tests of gas engines of outputs ranging from 500 to 5,000 b.h.p. show, the authors state, that the actual consumption of fuel per unit generated, exclusive of no-load losses, is approximately 1 lb. per kw. hour for any output from no-load to full-load. There is thus only the one curve drawn for the gas engines in the diagram.

For the maximum demand, load factor, and distribution efficiency assumed, the units generated per annum will be

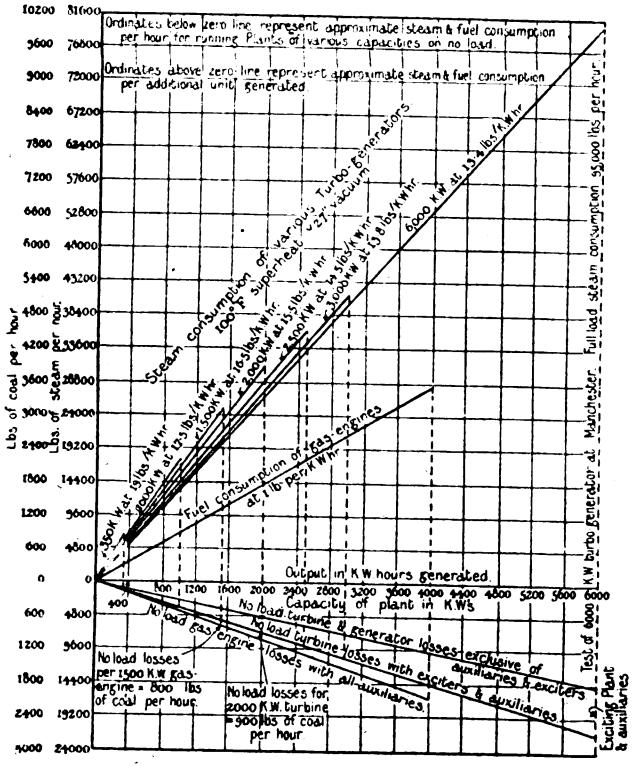

FIG. 2.

21,000,000. It is seen from Fig. 2 that for a 2,000-kw. turbo-generator the steam consumption per unit generated is 15.5 lbs., or, assuming evaporation of 8 : 1, 1·94 lbs. of coal is used per unit generated. The no-load losses are taken from the curve as 900 lbs. of coal per hour.

In ascertaining the running costs, allowance has to be made for banking of the boilers, and the authors have employed the following method for estimating the number of hours the boilers are banked and the number of hours the sets are run. The curve in Fig. 3 is calculated from a mean of the 365 daily load curves, and shows the number of hours per day the station is running at various loads. Thus, it is seen that the plant only supplies above 5,000 kw. for about two hours a day, that for six hours a day the load is 3,000 kw. or over, and that the minimum load is about 900 kw. It will be remembered that of the five 2,000 kw. sets, two were practically set aside for overhaul and stand-by. The remaining three sets would, as seen by the curve, be running two hours a day, part of the time on overload. For seven hours a day two units would be running, and for the remaining 17 hours only one set would be running. The total engine-hours per day would thus be 35, or 12,800 hours per annum. Similarly, the banked boiler-hours per day would be 45, or 16,800 hours per annum. From this the authors give the following figures for the annual coal consumption :—

21,000,000 Units at 1·94 lbs.	... ...	18,170 tons
12,800 Engine hours at 900 lbs.	... ...	5,140 tons
16,800 Banked boiler-hours at 448 lbs.	...	3,330 tons
Making a total of	... ...	26,640 tons

This the authors multiply by 1·25, which they call the "discrepancy factor." It is taken to represent the ratio of the actual ascertained fuel consumption under day-by-day working conditions, to the theoretical consumption based upon test results. The discrepancy is accounted for by variations in the quality of the fuel, by fuel utilised in heating up cold boilers, by the gradual fouling of boiler tubes, condenser tubes, &c., between cleaning periods, by errors of judgment as to the correct time for running up and shutting down plant units, and other seemingly small details which in a well-managed station receive constant attention, but the effects of which cannot be entirely eliminated.

Multiplying by this discrepancy factor of 1·25, the total of 33,300 tons of fuel per annum is obtained, representing 3·55 lbs. per unit generated, or an overall "thermo-dynamic efficiency" of 7·4 per cent.

The corresponding figures for the gas plant are :—

21,000,000 Units at 1 lb. of coal	... ...	9,360 tons
17,450 Engine hours at 800 lbs.	... ...	6,230 tons
85,000 Banked-producer hours at 50 lbs.	...	782 tons
Making a total of	... ...	16,372 tons

Multiplying this by the discrepancy factor of 1·25 gives 20,645 tons of fuel per annum, equivalent to 2·18 lbs. per unit generated, or an overall thermo-dynamic efficiency of 12 per cent.

Since the above estimates were prepared the authors have obtained actual fuel consumption results from a number of modern steam and gas installations, which they have embodied in a table as an appendix to their Paper. According to the mean of these figures, the authors' estimate of the thermo-dynamic efficiency of the steam station, in their estimates as above given, is 10 per cent. too high, and for the gas station 10 per cent. too low.

Returning to the gas station, the authors make allowance for the sulphate of ammonia produced as a by-product. They estimate that approximately 71 per cent. of the total coal consumption would be gasefied in the ammonia producers, and, making an allowance for expenditure on sulphuric acid (one ton of the sulphuric acid to each ton of sulphate of ammonia produced), and on packing, the total amount credited on the sale of sulphate of ammonia is £5,524.

The cost of oil, waste, and stores are taken at 0·005d. per unit for the steam plant and 0·0154d. per unit for the gas plant. In estimating the amount of water required, the authors have assumed that 3 per cent. will be evaporated from the cooling towers. They take it that 288,000 gallons of cooling water per hour will be required for each steam unit, and the cost of 3 per cent. of this at 6d. per thousand gallons works out to £2,760 per annum. In the case of the gas engines, about 12 gallons of cooling water per kw.-hour is required, and an addition has also to be made for the water consumption for the producers, which is taken at 12,700,000 gallons per annum. Assuming the same evaporation as before in the first item, the total water used will be 22,200,000 gallons, and its cost £555.

The labour charges are taken at £49 1s. for steam plant and

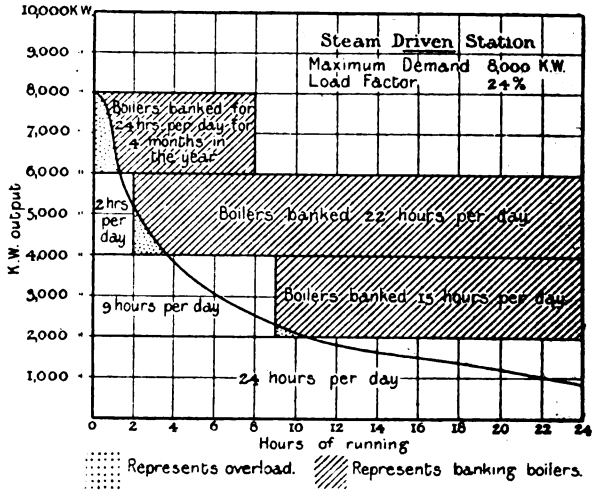

FIG. 3.

£61 5s. for gas plant per week, the latter including seven "ammonia-recovery" hands at 30s.

On the question of repairs, the authors state that with large gas engines the most serious risk is fracture of the piston or the cylinder liners. These troubles they say, however, are fast disappearing, although they were somewhat frequent in some of the earlier large gas engines. The actual wear and tear of the moving parts, they think, will be smaller in a gas engine than in a steam turbine. At one time it was thought that the wear on the exhaust valves would be considerable, and water cooling was resorted to, but Messrs. Ehrhardt and Sehmer came to the conclusion two years ago that this was an unnecessary complication; at the Manchester Exhibition an exhaust valve was exhibited which had been taken out of a 2,000 b.h.p. single-tandem engine after 466 twelve-hour shifts had been run, and it showed no sign of wear. The cost of repairs for the 10,000-kw. gas-

Digitized by Google

driven station, including auxiliaries and buildings is taken at £4,000 per annum, or 0·046d. per unit generated, and the same figure is assumed for the steam station.

The following table of annual costs is thus arrived at by the authors, which, it will be seen, gives two totals, one allowing 10 per cent. for interest and depreciation and the other only 6¼ per cent. :—

	Gas. £	Steam. £
Total cost of coal at 12s. per ton ...	12,280	19,968
Less sale of sulphate of ammonia ...	5,524	—
Net cost of coal	6,756	19,968
Oil, waste, and stores	1,345	438
Water	555	2,550
Labour	3,180	2,590
Repairs	4,000	4,000
Interest and depreciation at 10 per cent. on capital	17,687	13,952
Total cost	£33,523	£43,668
Total cost per unit	**0·383d.**	**0·498d.**
Total cost, **allowing 6¼ per cent. for interest and depreciation**	£26,900	£38,428
Total cost per unit	**0·306d.**	**0·438d.**

The cost per unit, it is seen, is thus worked out to 45 per cent. greater in the case of steam plant than in the case of gas plant when the lower figure is taken for interest and depreciation.

The authors next take the opposite extreme case, in which the generating station has a load factor of only 10 per cent., and fuel can be obtained at 8s. per ton. In this case they assume a smaller station, namely, one with a maximum output of 4,000 kw., and in this example the use of sulphate of ammonia-recovery plant is not justifiable. Under these conditions they

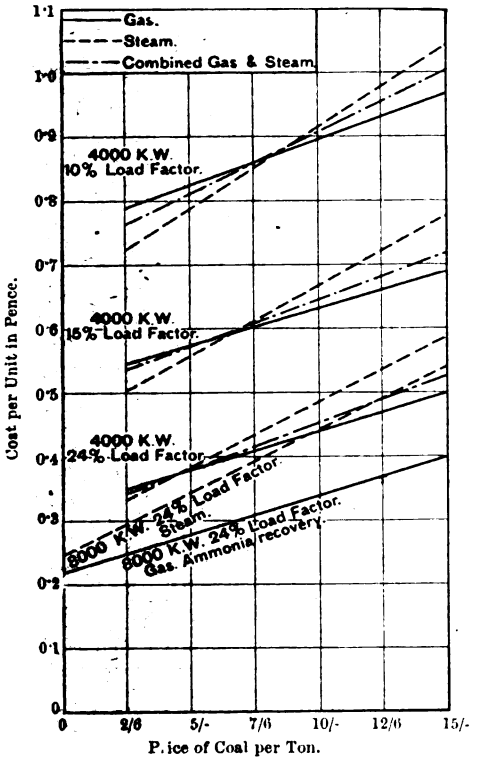

FIG. 4.—COMPARATIVE COSTS WITH GAS, STEAM, AND COMBINED GAS AND STEAM PLANTS, ASSUMING 10 PER CENT. CAPITAL CHARGES.

find that the saving in fuel effected by using gas engines is little more than sufficient to pay the 10 per cent. interest and depreciation charges. They compare three alternatives in this estimate : (*a*) a station with five 1,000 kw. steam turbo-generators, (*b*) one with seven 700 kw. gas engines, and (*c*) a combined station with four 1,000 kw. turbines and two 700 kw. gas engines. On the basis of 10 per cent. for interest and depreciation, the costs per unit generated come out to 0·868, 0·867, and 0.868. With 6¼ per cent. for interest and depreciation, instead of 10 per cent., the combined station shows an overall economy of 3 per cent. over the steam plant, and the "all-gas" plant an economy of 6 per cent. over the steam plant.

It is thus seen that, under no conditions is it worth while, in putting down a new station of this size, to instal a combination of steam and gas plants, but the authors emphasise the fact that this applies only to new installations, and they think there are many existing stations equipped with comparatively inefficient plant in which a large economy would be effected by installing one or more gas engines to be used for the flat portions of the load curve. This conclusion differs from the opinion expressed by Mr. Andrews in an article which appeared in ELECTRICAL ENGINEERING, of October 24th, 1907. Mr. Andrews explained

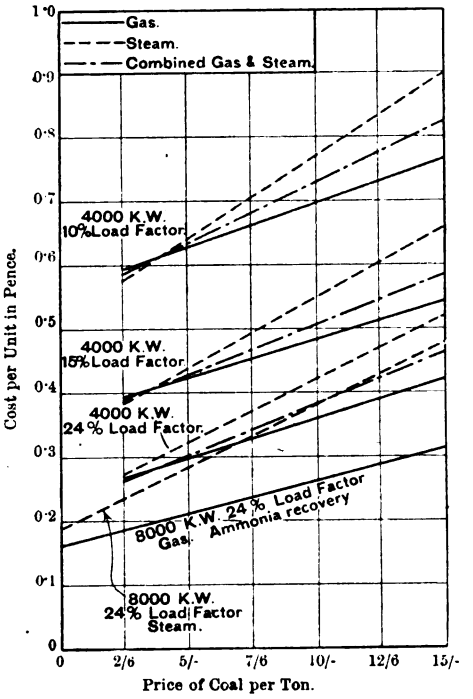

FIG. 5.—COMPARATIVE COSTS WITH GAS, STEAM, AND COMBINED GAS AND STEAM PLANTS, ASSUMING 6¼ PER CENT. CAPITAL CHARGES.

that, on his obtaining closer quotations for both steam and gas plants since he wrote that article, the capital cost of the gas plant came out at 27 per cent. instead of 43 per cent. higher than the steam installation.

Figs 4 and 5 show graphically the comparative costs of the three classes of plants; in the first case with 10 per cent. allowance for capital charges, and in the second case 6¼ per cent. It will be seen that in the curves the costs are worked out for different load factors and for various prices of coal.

DISCUSSION IN LONDON.

Mr. W. B. WOODHOUSE (Yorkshire Electric Power Co.), while recognising that the authors had made out an extremely strong case, proceeded to criticise a number of their figures and bases of argument. Referring, first, to the table comparing actual fuel consumption of a number of modern gas and steam stations, which is contained in one of the appendices to the Paper, and of which mention is made in our abstract, Mr. Woodhouse said that his station was not included, and that Mr. Gripper, of the Lancashire Power Co. informed him that there was another station left out also fitted with modern steam plant, and the inclusion of these figures would have improved the averages considerably. Then, in this table there was a load factor of 99 per cent. for one of the gas plants, and on the whole he did not think the authors wished the table to be taken too seriously. Probably they would prefer that he should take the figures for coal consumption given in the Paper, namely, 3·55 lbs. for steam, as against 2·18 lbs. for gas. He was not prepared to agree that where 12s. per ton was paid for coal for producer plant that they would necessarily have to pay the same for steam plant. Producers were extremely difficult things to operate, and it was necessary to be very careful in choosing the coal in order to avoid tar getting into the producers, whilst coal with a large percentage of nitrogen was no good for by-products. He would put the cost of coal for steam plant at less than that for producers, whatever the district. A by-product producer cost a good deal more, and was a good deal more complicated than a non-recovery producer, but whichever type was used, if dust and tar got into the cylinders these would go very rapidly, and greater trouble would be experienced with the auxiliaries than with the producer itself. On the question of boiler stand-by losses, Mr. Woodhouse said that it was now well known that steam boilers often had as high efficiency at half-load as at full load; in fact, it might be higher in some tests, perhaps due to faulty design. A producer, however, would not stand forcing. Apart from questions of costs, there was the question of the

Digitized by Google

size of units. The authors took a station of 8,000 kw., but whilst this was a fair sized station, it was obvious that with 20,000 kw., or even 16,000 kw., the comparison would have been more favourable to steam turbines. With gas engines, as with motor-car engines, increasing the diameter of the cylinders gave trouble; the volume was as the square of the diameter, whilst the cooling surface was as the first power of the diameter. The authors gave 1,000 h.p. per cylinder as the limit, and he rather thought this was a good limit. At the same time, it did not compare with the largest size turbine, and if they doubled the size of the station and doubled the number of gas engines the capital expenditure was doubled, whereas with turbine stations the capital expenditure would not be increased by more than 50 per cent. or 60 per cent. if the station were doubled, and this altered the comparison very considerably. The authors were rather fond of small units. They proposed 20 boilers of 10,000 lbs. evaporative capacity, whereas the modern practice would be to put in boilers of 30,000 lbs.; neither did he think it quite fair to suggest that the average engineer would put in an economiser to each boiler. Twenty little economisers and 20 little boilers would make an extremely expensive station to run, and was a very sad waste of capital. Mr. Woodhouse also objected to the use of town's water and cooling towers in a modern station, and pointed out that by capitalising at 10 per cent. the sum of £2,550 per annum spent on water in the author's estimates, and adding the sum of £6,900 allowed for the cooling towers, a figure of £32,400 was reached, far exceeding the extra cost of purchasing a site where water was available for condensing. Making what he thought were proper reductions for water, and correcting the estimates otherwise on the basis of actual figures taken from practice, he brought the costs down to 0·456d. for steam, and 0·47d. for gas. His chief alteration in the total for gas consisted in doubling the sum allowed for repairs of the gas-engine plant.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham Corporation) said he was at present engaged in drawing up a scheme for a big extension in Birmingham, and had been getting figures for gas plant in order to compare them with steam plant. Although several of the authors' figures were open to severe criticism, yet he thought they had done their best to put the case for both sides fairly. He disagreed with the authors on the question of overload capacity, for they had taken 10 per cent. as the overload capacity for gas, and compared this with 33⅓ per cent. overload for steam plant. He thought that neither of these figures were suitable for the generator. Generators, as generally installed now, were reckoned to have 25 per cent. overload for two hours, and this was governed by the temperature rise of the machines more than by anything else. If they only allowed 10 per cent. overload capacity they were wasting the capacity of the generators to the extent of 15 per cent., whilst 33⅓ per cent. would mean that the generators would have to be considerably larger than was necessary. Although the figures for repairs were difficult to criticise, he thought they erred on the light side. He would have anticipated that the repairs for a gas engine would be, with its much heavier internal strains, and possibly greater wear and tear in the parts, larger than with steam plant. He was not quite clear whether the figures for the producer plant included repairs. He did not see why the cost of gas engines should be so much higher than that of reciprocating steam engines, but perhaps when they became more generally used the cost would go down. The figure for water consumption with steam plant was very high, but even this only counted the cost of water lost in evaporation and in the cooling towers, and no mention was made of the make-up water for the boilers. He had recently inspected several large gas-engine stations on the Continent, and he was very much struck with the quiet running of the engines, their simplicity, and the apparent ease with which they were handled. There was no doubt that these engines were perfectly satisfactory for the parallel running of alternators. He saw one station which was connected up with a number of others, and there was a total of 50,000 h.p. running without trouble on one large network, some steam, and some gas. He had also examined one of these engines which had been in use for three years, and the internal parts were in a much better condition than many steam engines which had been running for the same period, and for this reason he thought that repairs on these engines should not be so very much heavier than with steam plant. The repairs would come out heavier on the producer plant.

Mr. E. J. FOX (Willans and Robinson) said he must differ with Mr. Chattock on the point of overload capacity. To get the best results out of the turbine it was fairly generally agreed that two things were necessary, namely, to run the turbine as continuously as possible, and to take advantage of the very heavy overload which turbines would take, even to the extent of putting on an alternator with an overload capacity of between 50 per cent. and 100 per cent. Although this might sound ridiculous, it was being done, and with undoubtedly good results. At Leeds they had put in two turbines solely on the ground of capital cost. At the time the particular order was placed there was practically no difference in steam consumption between turbines and reciprocating engines. But the actual difference in running was represented by 200 lbs. of coal per week. This must be accounted for by the fact that the steam turbine lent itself more easily to meeting the various conditions of a lighting load, and the result was shown in the steam economy. A very similar result, although not quite so pronounced, had been obtained by Mr. Seabrook at West Ham. The coal there had gone down practically 2 lbs. per kw.-hour during the last two years, and although this could not be credited solely to the economy of the turbine, it was undoubtedly due to the flexibility with which it adapted itself to the conditions. For this reason he should say that to deal with the authors' load of 21,000,000 units per annum, five 2,000 kw. sets were a great deal more than were required. At West Ham one set of this size last year generated 9,000,000 units. He would suggest four 2,500-kw. sets, each with alternators capable of giving an overload from 50 to 60 per cent. continuously. The greater capital cost of the generators was negligible, and, taking the plant as a whole, it would be possible to reduce the figure of £159,000 capital cost to £100,000, and this, he thought, was the correct figure to be compared with £176,000 for gas plant. With regard to working costs, he would not quarrel with the coal consumption, because this was the one point in which the gas engine was at an advantage, but he quarrelled with the labour. If they deducted from the labour set aside for gas plant the amount necessary for working the auxiliary plant and the ammonia plant, the actual cost was within a few shillings of that for the steam-turbine plant. It was inconceivable that the labour for running seven gas engines would be anywhere near as small as that for running four or five steam turbines. Neither did he think that the authors wished to be taken seriously when they stated that the repairs were nearly as light as for steam turbines. A good deal had been said with regard to maintenance of turbines, but he could give some figures on this point. Taking an output of 200,000 h.p. of turbines over a period of four years, the actual cost of maintaining the turbine and condensing plant was 6d. per kw. per year. The sum of £4,000, therefore, as given by the authors for the maintenance of their five 2,000-kw. sets was very excessive. His next point was that the authors put forward 10 per cent. as adequate for interest and depreciation, but surely it could not be argued, allowing 5 per cent. for interest, that 5 per cent. was sufficient to cover depreciation on either gas engines or steam plant. If they were spending their own money, they would want to replace the plant with something else in ten years, so that 5 per cent. was a very inadequate figure. Finally, said Mr. Fox, the most eloquent testimony against the adoption of large gas engines was the remark made by Mr. Andrews, that a small gas engine would work as economically as a large gas engine, and he thought that this was really where they ought to stop.

Mr. PERCY R. ALLEN (Castner-Kellner Alkali Co., Ltd.) said that the proposed lay-outs of both the steam- and gas-driven stations in the Paper were on the lines that would no doubt be adopted by engineers familiar with the latest practice. He mentioned, however, that it was unnecessary for the producer plant to be adjacent to the power-house, if, for instance, it were convenient to put the producer plant on one side of a railway or canal and the power-house on the other, since there was no loss from condensation as in main steam pipes. Although the proposition of making one-half of the producer plant work with recovery and the other half without had been several times put forward by the Power Gas Corporation, it was by no means certain that it would not pay to put in rather larger producers with the recovery plant all through, and to sacrifice a little ammonia during the periods the producers had to be overloaded. Mr. Allen next offered some suggestions for improvement in some details of the authors' proposed lay-out for the gas station. Among other things he said that the authors had provided for steam-driven exciters, but the blowers, air compressors for starting, and the lighting circuit of the station should also be capable of being driven by independent coal-fired boilers, particularly if separate groups of producers were not provided. The steam from the small engines could be used for working the sulphate-evaporating apparatus, and any surplus could be turned into the producers or used for heating the buildings in winter. The bulk of the extraneous low-pressure steam required for the producers would, of course, be produced by exhaust-heated steam boilers, which also acted as effectual silencers to the gas engines. Beyond the alternative steam-driven plant, already referred to, there was absolutely no necessity for spare steam plant; this was the speaker's personal experience extending over six years with a 10,000-h.p. Mond recovery plant, and, he added, many large gas-driven stations could be seen in Germany without any steam reserve. Mr. Allen entirely agreed with the authors in their recommendation as to the size and speed of the engines, whether they were four-cycle or two-cycle. Engines running at from 90 to 100 r.p.m., he said, seemed to have found most favour on the Continent, and gave singularly little trouble. The Snow pump gas engines working in California gave 5,400 h.p. with four cylinders, and some Körting engines were now being constructed in Germany intended to develop 2,200 h.p. in a single cylinder. A combination of these arranged twin-tandem would produce 8,000 h.p., but the station would have to be a very large one to justify this being adopted as the unit. From the gas-consumption point of view alone, perhaps the most economical arrangement was to have fair-sized units, say, 3,000 h.p. each, and then one or two other smaller engines, which were

Digitized by Google

multiples and sub-multiples of the main unit, the smaller ones being put on and off as the load varied. The speaker had found this very convenient in a continuous-current station, but it involved a good deal of switchboard attention, and, on the whole, the arrangement proposed by the authors would seem to meet the case, both as to the size of the units and facilities for dealing with the various loads. As far as repairs and renewals were concerned, Mr. Allen had looked up some actual figures, and found that the change from steam to gas effected a saving of about £30 a week; when the steam station was producing 25,000,000 units per annum the repairs and renewals for boilers, pipes, and auxiliaries had come to £45 per week, and the repairs to the producers, ammonia-recovery plant, and auxiliaries were now covered by £15 per week. There was also no reason to believe that a large gas engine running at a moderate speed and coupled direct to a generator would depreciate more rapidly than a steam engine. The writer had had two 700 h.p. two-cycle engines running for over six years, and the output was as good as the day they started. When the cylinder liners got worn down they would be simply bored out and others fitted in their places. There was, however, one point in connection with the gas-engine station that should be taken into account, viz., the winding of the generators should be very thoroughly and carefully insulated, preferably in a vacuum-impregnating machine, as, whatever might be said to the contrary, the atmosphere in a gas-driven station does have a deteriorating effect on the insulation. Coming now to the capital expenditure, the figure given of £17·68 per kw. installed came out almost exactly the same as that arrived at from the examination of some very close tenders obtained by the speaker last year for a 1,000-kw. plant, and the design could easily have been modified to bring this down to £17, allowing a good margin for contingencies. On the other hand, he was inclined to think that some of the labour figures were rather under-estimated. No mention was made either of any charges for supervision by a chemist, which, said Mr. Allen, was very desirable. At Westernpoint the whole of the producer-recovery plant was worked under the supervision of a highly-qualified chemist, and this installation was one out of two Mond plants, where the highest ammonia-recovery results were obtained. The writer was not at liberty to give the actual cost of power at this installation, but the figures given by Mr. Highfield last year before the House of Lords Committee (ELECTRICAL ENGINEERING, Vol. III., p. 939) might be taken as a safe estimate of the cost of running a 8,000-kw. plant continuously, and taking into account that the authors assume 12s. as being the price of coal, their estimated generating costs would be found to agree very closely with actual installations where the cost of coal is lower and the yield of sulphate somewhat more. In conclusion Mr. Allen referred to the possible shortage of coal in the course of years as a reason for employing engines which would save fuel, "in order to do our shivering descendants the minimum of injustice."

The discussion was adjourned until Thursday, February 25th, when it will be resumed by Mr. H. A. Humphrey, one of the champions of the large gas engine.

We hope to report the discussions in Dublin and Manchester in our next issue.

The Electrical Trades' Benevolent Institution.—The date of the dinner for the benefit of this Institution is now definitely fixed for Tuesday, March 30th.

"The Electron."—The January number of this publication, the magazine of the Siemens' Stafford Institute, contains portraits of Mr. Lee Murray, formerly Works Manager at Stafford, and of Mr. F. W. Schiller, Chief Engineer of Siemens Bros. Dynamo Works, Ltd. The former has only just left the Company, and a sketch of his career is included in this issue of the magazine. Among the other contents is the first instalment of a lecture by Prof. W. F. Barrett on "Dowsing for Minerals and Water," a special article on the International Electrotechnical Commission, by Mr. C. Le Maistre, with a group portrait of the members, the continuations of "Reminiscences of Life in Germany," by S. P. S., and "Secular Education: A Reply," by P. O. Powell. Some notes on the design of large castings, short reports of various debates and meetings of the different societies, and items of local interest are also included.

Single-phase Railways.—We understand from Messrs. Siemens Bros. Dynamo Works that the total length of railway lines equipped and under equipment for electric traction with Siemens' single-phase apparatus amounted to over 360 miles at the end of 1908. Examples of these are the Heysham-Morecambe section of the Midland Railway (ELECTRICAL ENGINEERING, Vol. III., pp. 885 and 921) and the Vienna Baden Railway (ELECTRICAL ENGINEERING, Vol. I., p. 655, and Vol. II., p. 929). Among those under preparation are the Parma Provincial, the Wiesental (Basel-Schopfheim), the Spiez-Frutigen, and Vacz-Budapest-Gödollö Railways. A 1,000-h.p. experimental locomotive with two 500-h.p. 15-cycle motors, and for a trolley wire pressure of 10,000 volts, is also in preparation. It is interesting to note that of the fourteen railways included in the above, seven are supplied at a frequency of 25 cycles per sec., and seven at 15 cycles per sec.

CATALOGUES AND PAMPHLETS RECEIVED

[Readers applying to any of the under-mentioned firms for copies of the catalogues or pamphlets referred to are requested to mention "Electrical Engineering"].

ELECTRIC HEATERS.—An extremely attractive show-card has been received from the Electric & Ordnance Accessories Co., Ltd., Chester Road, Aston, Birmingham, dealing with their "Eclipse" electric heaters, which are of the induced draught type. The firm inform us that, despite the rather unsatisfactory position of the electrical trade at the present time, the large demand for these heaters is well maintained.

AUTOMATIC SWITCH FOR ADVERTISING DEVICES.—Prices of the various sizes of the "Sun Thermo-blink Flasher" are given on a card issued by the Sun Electrical Co., Ltd., of 118-120 Charing Cross Road, London, W.C. This switch consists of two fixed metal strips inclined to each other and secured together at one end. A heating coil is arranged on one strip, and this is intermittently short-circuited by the movement caused by the expansion of the heated limb. Contact is made and broken between a fixed screw and the joint between the two strips.

DESK TELEPHONES.—A pamphlet from Messrs. Fordham & Co., Ltd., of Kingsway, London, W.C., contains particulars of a useful adjustable extension bracket for desk telephones. The length of the extended bracket is 26 in., and as it rotates round the supporting post a wide range of action is obtained.

DYNAMO & MOTORS.—Messrs. Marples, Leach & Co., Ltd., of Adnil Building, Artillery Lane, London, E.C., are publishing a regular monthly list of motors and dynamos in stock. The list for the present month includes a large number of machines, from the smallest sizes to those of 100-h.p. capacity and over. Shunt- and series-wound motors for continuous-current circuits, and single- and polyphase-induction motors are represented by several hundred examples of machines of various pressures and speeds. The type is stated in each case, so that reference to the standard catalogue will enable the general particulars of any particular machine to be ascertained. To those requiring machines at short notice this list should prove most valuable.

IRON-CLAD SWITCHGEAR.—Some particulars of several different patterns of iron-clad switches and fuse-boxes are given in a pamphlet issued by the Electrical Co., Ltd., of 121 Charing Cross Road, London, W.C. The switches have quick double break with parallel action and interlocked cases. Some neat patterns of iron-clad fuses with porcelain bases and phosphor-bronze contacts are listed. Water-tight distribution boards of the iron-clad pattern with spring-clip fuses are also included in this pamphlet.

ARC LAMPS.—A pamphlet from Messrs. Marples, Leach & Co., Ltd., gives in an abridged form a large amount of information respecting the various patterns of arc lamps supplied by this firm. Among the flame arc lamps listed is the "Rebofa" lamp, in which the impregnated carbons are arranged vertically one above the other so as to obtain a more general distribution of the light than is possible with the converging carbon pattern. The voltage across the arc is only 30 volts, so that six lamps can be connected in series on a 200-volt circuit. A 12-ampere flame carbon lamp of this pattern with an overall length of 40 in. burns 25 hours on one pair of carbons. These lamps can be obtained for either A.C. or D.C. circuits. Flame lamps of the converging carbon type are also listed. Particulars of the "Regina" lamp, in which the mechanism is so simplified as to consist of one working part only, and which burns from 200 to 300 hours on one trimming, are given in the section relating to enclosed arc lamps. In this section the "Helia" lamps, taking only from 2 to 7 amperes, and for working singly on 100- to 150-volt circuits are also described. Finally, special lamps for indirect lighting, colour matching, &c., are listed. Full information with regard to carbons and other accessories is included in this pamphlet.

ENGINE-ROOM ACCESSORIES.—A section of the catalogue of Messrs. Elliott Bros., of Century Works, Lewisham, S.E., containing particulars of a number of engineering instruments, is to hand. Among the speed indicators listed are the Young mechanical indicator, and various electrical combinations, comprising a magneto-generator and different indicating and recording instruments on the voltmeter principle. The application of these instruments for recording the speed of ring-spinning frames is described. Other useful accessories, such as micrometers, planimeters, recorders for steam and water pressure, pressure and vacuum gauges, and steam-engine indicators are included in these pages. The last named include the Richards, Darke, and Simplex patterns.

IGNITION CELL TESTER.—A leaflet, describing a new accumulator discharge meter is to hand from Mr. G. Braulik, of 8 Lambeth Hill, London, E.C. This instrument consists of a small low-resistance voltmeter of the "watch" pattern with a range of from 3 to 5 volts. The resistance is so adjusted that the voltmeter takes the normal discharge current, and, therefore, indicates the terminal pressure of the cell when discharging. This useful little instrument is being put on the market at the price of fifteen shillings for all three sizes, namely, for currents of 1·5, 3, and 6 amperes respectively.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 11th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

22,581/07. **Storage Battery Sub-stations on A.-C. Systems.** A. M. TAYLOR. In order to provide for the peak loads on A.-C. systems, storage batteries may be connected with the system through suitable converting machinery and charged or discharged according to the value of the load. According to the present invention, it is proposed to reduce the capital cost of such battery sub-stations by installing at first a very few cells of very large capacity, and subsequently adding similar groups of cells in parallel, until the peak load is such that the number is sufficient to make up the full D.C. pressure. When in parallel, the cells are connected to the system through special low-voltage converters (25 to 50 volts) fed from the H.T. mains by double transformation. Such machines would be provided with two commutators in parallel, and, by suitable reconnections, could be used as boosters or generators if the parallel grouping of the cells were changed to series grouping. The transformers could also be constructed so as to be easily adapted to the higher secondary voltage. Various other means of rendering the converting plant suitable for a full D.C. pressure of 400 to 500 volts, as well as for a low battery pressure of 25 to 50 volts, are described in this specification. Four claims, eleven figures.

1,596/08. **Flame Arc Lamp.** H. E. MOUL. In flame arc lamps with converging carbons, the ash is sometimes deposited on the tips of the carbons, preventing the arc from being struck after it has been extinguished. The present invention is for a feeding mechanism in which the carbons are fed down alternately instead of simultaneously, so that a rubbing action is produced between the fixed and the moving carbons to scrape off any deposit. This alternate feed is effected by supporting the two carbons by chains which pass round two slotted pulleys threaded loose on the same spindle, and provided with ratchet wheels. Fixed pawls prevent the backward rotation of these wheels, and the forward movement, which is in opposite directions for the two wheels, is caused by two pawls on a rocking lever. This lever is rocked by the series coil, which is only in circuit when feeding is necessary, but then gives the rocking motion continuously, as the plunger short-circuits the coil when it rises, and thus works up and down continuously. A shunt coil controls one carbon by means of a sliding collar in the usual manner. When the plunger of the shunt coil has risen to its full amount, it opens the short-circuiting switch of the series coil and allows the latter to operate the feeding mechanism until the arc has attained its normal length. A "blow" magnet to control the arc is provided, and this is arranged to insert a substitutional resistance when the arc is extinguished. Two claims, four figures.

2,707/08. **Manufacture of Metal Filament Lamps.** J. HOWARD. In the process of manufacturing metal filament lamps, after the filament has been mounted and the bulb exhausted, it is necessary to pass a much larger current than the normal working current through the filament in order to expel the absorbed gases. With high-voltage lamps, as, for example, a 250-volt lamp, a pressure of 350 volts may be necessary for this purpose, and it has been found that a discharge, which is detrimental to both the filaments and the vacuum, takes place between the filaments at the extreme ends. According to the present invention, when the filament consists of several loops in series, auxiliary leading-in wires are fitted solely for the purpose of running the lamps with the loops temporarily in parallel. A low pressure can then be used for the above operation, and there is no discharge. Three claims, three figures.

8,997/08. **Ventilation of Laminated Iron Cores.** A. R. LOW. Ventilating by means of ducts in the plane of the laminations is not always effective in consequence of the varnish or paper insulation. In the case of the cores of transformers and the poles of single-phase commutator motors where the field is alternating and not rotary, the ventilation is effected, according to this invention, by slots transverse to the laminations. These slots must be in the direction taken by the main flux, and must be narrow. They can extend the full length of the magnetic circuit. Connecting cross-pieces must be left, or the core can be made up of parts spaced by distance-pieces. Four claims, seven figures.

17,421/08. **Ventilation of Flame Arc Lamps.** KÖRTING & MATHIESEN AKT.-GES. In arc lamps with economisers, the vapours, instead of rising upwards, move laterally, and cause a deposit to be formed on the cold globe. To prevent this, the economiser is, according to this invention, surrounded by a cylindrical transparent chimney, and the vapours pass upwards through the annular space between the neck of the chimney and the economiser. Air enters at the bottom of the main globe, which is closed at the top, and rushes through the inner chimney, taking with it the vapours. The chimney is quickly heated, and is prevented from cooling by the body of air between it and the outer globe. Three claims, two figures.

17,752/08. **Switch for Advertising Device.** FRITZ LÜLING. This is a switch for automatically switching on and off three or more groups of lamps. It consists of a pivoted tube containing ether, and provided with bulbs at both ends. Two heating resistances or lamps, energised alternately, cause the ether to evaporate in the one bulb and to force the liquid ether into the other bulb which is then cooling, and a rocking motion is thus obtained. The particular feature claimed in this specification is the use of a stirrup-piece hung from the end of the rocking lever, under which is a rocking switch which is rocked in alternate directions on successive descents of the stirrup-piece, so that different circuits are connected up alternately. Two claims, four figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps: VERITYS, LTD., and WORSLEY [Flame arc lamps with converging carbons] 14,982/08.

Distribution Systems, Cables and Wires, Insulating Materials, &c.: HEITMEYER [Bricks for cable conduits] 1,672/08; BRITISH INSULATED & HELSBY CABLES, LTD., and COLE [Cable armouring] 15,641/08; LINKE [Locating faults in H.T. systems] 22,215/08.

Dynamos, Motors, and Transformers: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Dynamo-electric machines] 2,244/08; HALL [Ventilation of machines] 7,854/08; AUVERT and FERRAND [Rotary converters] 15,864/08.

Electrometallurgy and Electrochemistry: BRITISH THOMSON-HOUSTON CO. (*General Electric Co., U.S.A.*) [Furnaces] 1,470/08; KELLER [Furnace-electrode connections] 12,654/08.

Ignition, Electric: HAILWOOD [Miners' lamps] 28,255/07; ZÄHRINGER [Rotary interrupter] 18,756/08.

Instruments and Meters: CHAMBERLAIN & HOOKHAM, LTD., and HOLDEN [Meters] 10,893/08; HARTMANN & BRAUN AKT.-GES. [Hot-wire instruments] 26,449/08 and 26,450/08.

Storage Batteries: VAN RADEN & CO., AND METZ, 25,264/08.

Switchgear, Fuses, and Fittings: DRAKE, BARNES, AND DRAKE & GORHAM, LTD. [Switches] 2,281/08; HEADLEY, WALTON, AND LAWLEY-PINCHING [Switches] 12,170/08.

Telephony and Telegraphy: SCHIESSLER [Wireless telegraphy and telephony] 1,848/08; CREED AND COULSON [Tape perforating machine] 1,947/08; AMALGAMATED RADIO-TELEGRAPH CO. [Wireless telegraphy] 2,206/08; SOC. DES TELEGRAPHES MULTIPLEX (*Systeme E. Mercadier*) [Mono-telephone relays] 6,928/08; ELLISON AND JACOBS [Telephone call apparatus] 12,507/08; TARDIEU [Microphones] 16,788/08; KITSEE [Telegraph relays] 20,300/08; SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges*) [Signalling telegraphs] 20,600/08; DANIELS [Telephony] 20,671/08.

Traction: MOUNTAIN & GIBSON, LTD., AND RENISON [Tramcar wheels] 28,164/07; GOLLNICK [Tramcar life-guards] 24,222/08; KUTSCHER [Guard for trolley-wheel] 24,529/08.

Miscellaneous: ROSS [Vibration recorder] 12,156/08; HARTMANN & BRAUN AKT.-GES [Speed indicators] 22,105/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

TABLER [Disinfecting telephones] 1,493/09; CEREBOTANI [Telegraphic typewriter] 1,551/09; ALLGEMEINE ELEKTRICITÄTS-GES. [A.-C. commutator machines] 1,705/09.

Expired Patents

The following are the more important patents that have become void through non-payment of renewal fees:

Arc Lamps: A. ECKSTEIN and A. E. ANGOLD [Protection of shunt coils] 23,694/02; JANDUS ARC LAMP & ELECTRIC CO., LTD., and A. D. JONES [Lamp with two arcs in series] 22,838/04.

Dynamos, Motors, and Transformers: L. B. ATKINSON [Armature-windings] 19,213/00; WARWICK MACHINERY CO., LTD. (*General Electric Co., U.S.A.*) [Electrically-operated valves for turbo sets] 23,355/03.

Instruments and Meters: BRITISH THOMSON-HOUSTON CO., LTD. (*W. H. Pratt*) [A.-C. meters] 21,668/99; CROMPTON & CO., LTD., and W. A. PRICE [Electrostatic voltmeter] 23,443/03.

Switchgear, Fuses, and Fittings: R. BELFIELD (*A. J. Wurts*) [Circuit-breaker] 23,942(A)/96; S. WHIPP [Loose-handle circuit-breaker] 23,521/03; TANGE TOOL & ELECTRIC CO., LTD., and A. H. BATE [Automatic motor-starter] 22,832/04.

Traction: J. W. ALLEN [Overhead construction] 22,839/04.

Restoration of Lapsed Patent

An Order has been made restoring Patent No. 19,477 of 1899 granted to J. F. Simmance and J. Abady and relating to improvements in street-lighting apparatus.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

The Högner flame arc lamp patent, No. 23,606 of 1902, belonging to Messrs. Körting & Mathiesen, whose agents in this country are the Union Electric Co., Ltd., has been revoked, subject to an appeal to the High Court. In giving his decision the Comptroller held that, in considering whether a patented article was manufactured "mainly or exclusively" abroad, he must take into account the numbers of that article which are manufactured abroad in accordance with the patent, but not imported. The British Westinghouse Co. is appealing against the Comptroller's decision revoking the Bremer arc lamp patent. (Page 178.)

An improved form of the "Excello" flame arc lamp has been put on the market. There are two pairs of carbons, which are burnt in succession. A form of inner globe has also been developed, the purpose of which is to induce a strong draught through the globe to carry away the fumes. For street-lighting, the inner globe is moulded prismatically on the exterior, in order to obtain a greater horizontal illumination. (Page 179.)

In a Paper read recently in Birmingham by Dr. W. Lulofs, a method of carrying out the Kapp-Hopkinson circulation-of-power test on a single lap-wound continuous-current machine was described. The author gave two alternative arrangements, both of which, however, necessitated the employment of an auxiliary machine. Some effects of armature reaction in lap-wound machines, and their application to the design of a constant-current dynamo, were also dealt with in the Paper. In the discussion which followed, it was suggested that equalising connections were unnecessary in lap-wound machines. The effect of the magnetic pull produced by the unequal excitation of the poles for the purpose of the author's test was also discussed. (Page 181.)

A new pattern of electric coffee roaster, with an attachment for extracting sample beans at intervals, has recently been placed on the market. (Page 182.)

Under "Electrometallurgy and Electrochemistry," a method of recovering tin from scrap is described, and a note is given on a German patent for the production of calcium carbide in the induction furnace. (Page 182.)

Digitized by Google

Two large electric cranes recently installed at the works of the Tranmere Bay Development Co. are described in an illustrated article. (Page 183.)

A PAPER describing the electric main shaft winding plant supplied by the British Westinghouse Co. to the Maritime pit of the Great Western Colliery Co., near Cardiff, was read recently by Mr. G. Hooghwinkel. The winding drum is coupled to a slow-speed three-phase induction motor, and the flywheel equaliser consists of a continuous-current machine acting through the medium of a rotary converter. (Page 185.)

IT is announced that 20 per cent. of the amount paid for space at the Manchester Electrical Exhibition is to be returned to the exhibitors out of the profits, and 10 per cent. of the sums granted by the various companies and councils. (Page 186.)

IN a Paper read before the Rugby Engineering Society last Thursday, Mr. F. W. Carter drew attention to the relative importance of the rates of acceleration in different classes of railway service. After showing the necessity of a high value on urban and suburban lines, the author contends that the single-phase system is, on this account, less suitable for such work than continuous-current working. (Page 187.)

A RECENT article in an American contemporary gives some particulars of the Majorana system of wireless telephony with which experiments have been made in Italy. A water-jet form of transmitter is used, and the latest apparatus works with undamped waves from a Poulsen arc. (Page 187.)

THE annual dinners of the Leeds Local Section and the Students' Section of the Institution of Electrical Engineers were held last week. In the course of his speeches at these dinners, Mr. W. M. Mordey made some further statements with regard to British and German electrical engineering. It was suggested that the Leeds Local Section should in future be called the Yorkshire Section; we believe that the Institution is not averse to this proposal. The Old Students' Association of the Central Technical College also held their annual dinner last week. (Page 188.)

THE following are the subjects of some of the more important patent specifications, of which we publish abstracts this week:—A flexible connector for operating switches mechanically, by B. M. Drake, A. Barnes, and Drake & Gorham, Ltd.; the ventilation of motors and dynamos, by J. P. Hall; an electromagnet for use in continuous-current mercury meters, by Chamberlain & Hookham, Ltd., and S. H. Holden; the mechanical construction of flame arc lamps, by Veritys, Ltd., and F. S. Worsley; steel armouring for heavy trailing cables, by the British Insulated & Helsby Cables, Ltd., and F. A. Cole; combined hot-wire and resonance speed-indicators, by Hartmann and Braun, Akt.-Ges.; and apparatus for indicating faults on high-tension systems, by C. Linke. A Patent for apparatus for the electric ignition of miners' safety lamps, granted to W. Ackroyd and W. Best, expires during the current week after its full term of life. (Page 189.)

THE question of gas engines v. steam turbines, in connection with Messrs. Andrews and Porter's Paper, was discussed in Dublin and Manchester, both discussions being of a practical and technical nature. Several speakers gave their corrections to the authors' estimates. It was pointed out that the authors had included the cost of land, which was far greater in the case of the gas station, and their estimates for cooling water and their assumption of cooling towers were also objected to. Mr. Pearce stated that the turbo-alternators at Manchester were likely to cost far less in up-keep than the slow-speed reciprocating sets, so that the cost for repairs should not be taken the same for turbine plant as for gas plant. On the other hand, others spoke on the reliability of gas engines, and said that it cost very little to keep the producer plant in repair. (Page 191.)

A NEW scale of charges has been prepared by the Birmingham Electric Supply Committee, in which, in certain circumstances, the charge for lighting is as low as 2d. per unit.—The Board of Trade has refused permission to the Farnham & District Electric Lighting Co. to erect overhead wires.—The sum of £18,000 is to be transferred to the rates out of tramway profits at Hull.—The London County Council recommend that running powers should be granted to the Metropolitan Electric Tramways, Ltd., over the portion of the tramways in Harrow Road which are to be acquired from the company.—An experiment is to be made by the Poplar Council in wiring small houses free of charge, but without fittings.—The Local Government Board has now informed the Maidstone Corporation that a loan to defray expenditure previously incurred in connection with the electricity undertaking will be granted on condition that the principal is paid out of revenue.—The trackless trolley system is recommended in Middlesbrough on a circular route of 2½ miles.—Sir Alexander Kennedy has recommended the Oxford Corporation not to sanction the use of any surface-contact system.—A report has been presented at Weymouth in which it is stated that the trackless trolley system is not suitable for the district. (Page 193.)

THE Radcliffe Council require a 300-kw. generating set, motor generator, reversible booster, condensing plant, and switchboard extensions.—The Birmingham Electricity Committee recommend extensions to the value of £140,000.—Local Government Board inquiries have been held at Ilkley (£5,700) and West Hartlepool (£3,210).—Electrical stores are required at Barrow-in-Furness, Belfast, Colchester, Dundee, Heston and Isleworth, and Wrexham. (Page 194.)

THE report of Simplex Conduits, Ltd., for last year shows a net profit of £13,131.—At the meeting of the Waste Heat & Gas Electrical Generating Stations, Ltd., last week, it was stated that the arrangements have been made with the Newcastle and other power companies to take all the power which the company can generate.—Mr. Arnold Lupton, at the meeting of the Yorkshire Electric Power Co. last week, stated that they had now begun to work off the adverse balances of their early years.—The accounts of the Underground Electric Railway Co. of London for 1908 show a deficit of £11,836.—The National Telephone Co.'s report for the December half-year shows a net balance of £495,638. (Page 197.)

THE revocation of the Högner flame arc lamp patent, following closely on the revocation of the Bremer patent, was not unexpected, and although the matter is not ended until the appeals have been heard, these two decisions of the Comptroller possess already a great importance. In the first place they show what construction the Comptroller is placing upon the words in the new Act which stipulate that a patent is liable to revocation if it is worked "mainly or exclusively" outside the United Kingdom, and that the patented article should be manufactured to an "adequate" extent here. In considering the meaning of these words, the Comptroller takes into account the whole manufacture abroad—not only the importation into this country. This will doubtless be one of the matters on which the opinion of the High Court will be sought, and the other point which is clearly brought out by these decisions claims more attention at the moment. So far, the results of the revocation clause of the

Digitized by Google

new Act are disappointing. Briefly, it may be put that if the effect of the clause is merely to bring about the revocation of a number of patents, it is a failure, but that if its effect is to encourage foreign patentees to manufacture in this country instead of supplying the British market from abroad, it will be a success. In the case of the flame arc lamp patents, the immediate result is to facilitate the importation of flame lamps made in conformity with the Bremer and Högner patents. The owners of these patents may suffer, but the arc lamp industry in this country will not be the gainers. Our arc lamp manufacturers have for some time been able to produce excellent flame arc lamps, and they will gain practically nothing by being free to make use of the ideas in the two patents in question. On the other hand, prices will be brought down if there is an influx of competing arc lamps from abroad; and although we fully accept the Union Electric Co.'s statement in our correspondence column last week that their lamps are still protected by other patents, there is no doubt that the way has been opened for the free importation of competing lamps. If, notwithstanding, the decisions will in reality have no serious effect upon the Union Electric Co., we are unfeignedly glad, for there is no doubt that the electricity supply industry owes much to this firm for being the introducers of the first reliable flame arc lamp into this country.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 25TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster, when Messrs. Andrews & Porter's Paper on "The Use of Large Gas Engines for Generating Power" will be resumed.

FRIDAY, FEBRUARY 26TH.

Physical Society.

5 p.m. Meeting at the Finsbury Technical College, Leonard Street, City Road, E.C. Agenda:—(1) Prof. Coker, "A Laboratory Machine for Applying Bending and Twisting Moments Simultaneously." (2) Prof. Silvanus P. Thompson, F.R.S., and E. W. Moss, "On the Self-demagnetising Factor of Bar Magnets." (3) Prof. Silvanus P. Thompson, F.R.S., Exhibition of optical properties of combinations of mica and selenite films (after Reusch and others) in convergent polarised light. (4) Mr. Charles R. Darling, Exhibition of (*a*) a simple form of thermo-electric pyrometer for students' use, (*b*) a combined metre-bridge and potentiometer, with new tapping-key device, for pyrometric and general laboratory work, and (*c*) a new form of carbon-plate rheostat, suitable for control of small electric furnaces.

Northampton Institute Engineering Society.

5.45 p.m. Meeting at the Institute, St. John Street, Clerkenwell. Among the Papers down for reading is one on "The Trackless Trolley System of Electric Traction," by S. M. Hills.

Institution of Electrical Engineers: Manchester Section.

6.45 for 7.15 p.m. Annual Dinner at the Midland Hotel.

Institution of Civil Engineers.

8 p.m. Special Lecture by Dr. W. C. Unwin, F.R.S., on "Standardisation in Engineering Practice."

SATURDAY, FEBRUARY 27TH.

Northampton Institute Engineering Society.

7.30 p.m. Smoking Concert of Past and Present Day Students, at Stone's Restaurant, Ludgate Broadway, Ludgate Hill, E.C.

MONDAY, MARCH 1ST.

Institution of Electrical Engineers: Newcastle Section.

8 p.m. Informal Meeting at the Armstrong College. Paper to be read:—"The Electrical Equipment of Modern Battleships," by A. P. Chalkley.

Society of Arts.

8 p.m. Cantor Lecture III., by Mr. Leon Gaster, on "Methods of Artificial Illumination."

TUESDAY, MARCH 2ND.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology. Paper to be read:—"The Design of Small D.C. Machines," by B. E. Stott and J. Hargrove.

WEDNESDAY, MARCH 3RD.

"*Dynamicables.*"

7 for 7.15 p.m. Dinner at the Trocadero Restaurant, Piccadilly.

Institution of Electrical Engineers: Leeds Local Section.

7.15 p.m. Meeting at the Sheffield University. Paper to be read:—"Researches on the Magnetic Properties of a Series of Carbon Tungsten Steels," by T. Swinden.

Institution of Electrical Engineers: Students' Section.

7.45 p.m. Meeting at 92 Victoria Street, London, S.W. Paper to be read:—"Rheostats," by J. S. Messent.

THURSDAY, MARCH 4TH.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster. Paper to be read:—"Some Commercial Aspects of the Management of Central Electricity Supply Stations," by R. Borlase Matthews.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Paper to be read:—"Some Vacuum Tube Phenomena," by A. A. Campbell Swinton.

Rating of Tramways.—The Court of Appeal has upheld the decision of the Lancashire Justices that the Blackpool & Fleetwood Tramroad Co. shall only be liable to pay rates on the basis of a railway, viz., on one-fourth the rateable value, their line being on private land.

International Electrotechnical Commission.—It is stated that the invitation of the German delegates to the International Electrotechnical Commission to hold the next full meeting in Berlin has been accepted. The year 1910 has been suggested, but it is understood that although Berlin has been definitely decided upon as the meeting-place, the date of the meeting has not yet been agreed upon.

Stamp Duty on Tramway Co.'s Capital.—Before Mr. Justice Channell, in the King's Bench Division last week, a case was heard in which the Crown claimed payment of stamp duty on the capital of the Anglo-Argentine Tramways Co. The company was registered in 1871, with a capital of £800,000. In July, 1907, a resolution was passed authorising the increase of the capital by £5,000,000, but only £200,000 of this new capital was issued, and later a further issue, amounting to £2,800,000 was made. The company contended that stamp duty was only payable on the amount issued, whereas, on behalf of the Crown, the Attorney-General argued that the whole of the £5,000,000 authorised was dutiable. The court upheld this view, but a stay of execution was granted for three weeks. The sum involved is £12,500.

The Lighting of Victoria Embankment.—A short while ago the London County Council decided to dismantle the gas-driven generating station which supplied the necessary energy for lighting the Victoria Embankment, and to take a supply from the Charing Cross, West End & City Electricity Supply Co. Since supply was commenced, however, certain legal difficulties arose in consequence of part of the area being outside that of the Charing Cross Co. and in that of the London Electric Supply Corporation. As a result, agreements have now been entered into with both companies to light those portions of the Victoria Embankment within their areas, and, in the case of the latter company, also Westminster Bridge. The agreement in the case of the Charing Cross Co. is for four years at 1d. per unit, and 0·95d. per unit for a succeeding period of four years, and with the London Electric Supply Corporation, the agreement is for seven years at a rate of 1d. per unit.

Stamp Duty on Electric Supply Agreements.—In the Appeal Court last week judgment was given in the case in which the County of Durham Electrical Power Distribution Co., Ltd., appealed against a decision of the Commissioners of Inland Revenue in assessing a contract for electricity supply. The contract in question was with Messrs. Snowball, Son & Co., of Gateshead-on-Tyne, for a supply of electricity for seven years, there being a standing charge of £57 10s. per quarter, plus one penny per unit for all energy consumed, and ten shillings per quarter for meter hire. Such an agreement, the Commissioners of Inland Revenue declared, should be taxed with an *ad valorem* stamp duty of 2s. 6d. per £100, holding that it came within Exemption 3 of the Stamp Act, and that it related to the sale of goods. On the other hand, Mr. Dankwerts, K.C., for the company, argued that the contract was, if anything, exempt from even a 6d. stamp, and that there was an express exemption from stamp duty in favour of such agreements. Mr. Justice Channell, however, whilst thinking that it was not the intention of the legislature that the Stamp Act should do what the Commissioners of Inland Revenue claimed, yet in fact it did do so, and he found for the Commissioners, a judgment which, he said, was against his own personal opinion.

REVOCATION OF ANOTHER FLAME ARC LAMP PATENT

THE British Westinghouse Electric & Manufacturing Co., Ltd., inform us that they are giving notice of an appeal from the recent decision of the Comptroller-General revoking the Bremer arc lamp patent No. 18,786 of 1902.

In the meantime the Comptroller-General of Patents has decided, subject to an appeal to the Court, to revoke patent No. 23,606 of 1902, in accordance with the petition of Mr. G. Braulik. This patent, particulars of which we published on page 144 of our issue of Feb. 11th, was taken out by Mr. Paul Högner, Chief Engineer of the German firm of Körting & Mathiesen, whose agents in this country are the Union Electric Co., Ltd. Counsel for the patentees stated in the hearing that there is very little difference between the two patents, and that the mechanism shown in the drawings of the present patent is substantially within the Bremer patent.

It may here be mentioned that the Bremer patent anticipated the Högner patent by only two months—in fact, the Högner patent was filed during the interval between the filing of the provisional and complete specification of the Bremer patent. An agreement was, however, come to between the owners of the two patents by which each firm was allowed to manufacture under the other firm's patent.

In his decision, the Comptroller says that the Högner patent appears to be, in substance, anticipated by the Bremer, and that, as a matter of fact, in the arrangement between the German company and the Westinghouse company, the Högner patent was apparently held of very small account. No royalties were payable by the Westinghouse company (owners of the Bremer patent) in respect of lamps made under it, while, on the other hand, substantial royalties are said to have been paid by the German company for lamps manufactured under the Bremer patent. It was also stated that no proceedings had been taken under the Högner patent against infringers. In the circumstances, says the Comptroller, it is a mystery to him that the applicant was so anxious to revoke the Högner patent, and that the patentee should be so desirous that it should not be revoked, for it seems to him that the present patent has hitherto not been considered by its owners to be of any substantial value.

Soon after the proceedings for the revocation of the two patents had been commenced, the Comptroller suggested that, in order to save expense to both parties, the proceedings in respect of the two patents should be consolidated, but the patentee's agent objected to this because he said the arguments were different in the two cases.

The patentee's first contention in the hearing of the case was that the lamp was not manufactured under the patent anywhere, and that there was no "patented article" within the meaning of Section 27 of the Patents Act, since the patentee had claimed no protection under the patent, had taken no action against anyone under the patent, and had taken no royalties for manufacturing under it. With this view the Comptroller does not agree, holding that a patented article is an article described in the patent specification.

Counsel for the patentee next argued that, in the event of the preceding point being decided against him, the Comptroller should hold that no article manufactured abroad in accordance with the patent is a "patented article" within the meaning of Section 27 of the Patents Act, unless it is imported into this country. The Comptroller holds that this suggested limitation of the section is untenable, and that when a patented article is manufactured mainly or exclusively abroad, whether it is imported into this country or not, this section of the Act applies to it.

During his examination by counsel, Mr. Eck, the engineer and secretary of the Union Electric Co., "sprang upon" the applicant without previous notice the names of thirteen English firms which, he alleged, were manufacturing in this country lamps the mechanism of which he averred was similar to that of the lamp protected by the Högner patent, and he stated that, from his knowledge of the trade, he believed that the English manufacture of these lamps was greater at the present time than the importation of them. He put the proportion at about 60 to 40, and he estimated that the English manufacture of these flame arc lamps must exceed 40,000 per annum. He admitted, however, that neither he nor anyone on his behalf had written to a single firm protesting against infringement of the Högner patent. Colonel Crompton, who was examined as a witness for the patentees, stated that in his belief there was a round dozen of English manufacturers who were making arc lamps of the type to which the Högner patent related, and that between them he should have thought they made 50,000 lamps annually.

The Comptroller, who only heard Colonel Crompton's evidence under considerable pressure, now states that he should not have admitted this evidence, as the Patent Office rules require the patentee to leave his evidence at the Patent Office by way of statutory declaration before the hearing, so that the applicant may have an opportunity to lodge statutory declarations in reply. Nevertheless, even accepting Colonel Crompton's estimate, as well as Mr. Eck's, that 60 per cent. of the lamps were sold in the United Kingdom and the remaining 40 per cent. imported, the Comptroller does not consider that this shows that the patented article was not manufactured mainly abroad, because it would leave altogether out of account the number of these lamps which are made abroad and not imported into this country (including those manufactured by the German company, who have been stated by Mr. Eck to be the premier firm of arc lamp manufacturers in the world). The Comptroller, therefore, decided that the patented article is manufactured mainly outside the United Kingdom.

The next point is whether the patented article is manufactured to an adequate extent in the United Kingdom. The number of lamps manufactured by the Westinghouse Co. was given as between 500 and 600 a year, and this is not considered adequate by the Comptroller, having regard to the very large number of lamps imported, some, it was alleged, by infringers and some, it was admitted, by the patentee.

The only remaining question was whether the patentee had given satisfactory reasons why the patented article was not manufactured in this country to an adequate extent. On the point, the Comptroller says that it is out of the question for him to hold that a patentee may get rid of his responsibility for working a patent merely by granting a licence to work it to a firm who do not manufacture in the United Kingdom to an adequate extent, whilst he himself, in competition with his licensee, is importing far larger quantities than the licensee makes in this country. The Comptroller fails to see any good reason to prevent the patented article from being made in this country to an adequate extent by the patentee, since it has been manufactured in increasing quantities in this country by firms whom the patentee alleges to be infringers, who, it is to be presumed, would not have manufactured it if they did not make a profit by doing so. The Comptroller, therefore, fails to understand why the German company could not have manufactured it at a profit here also.

Subject to an appeal to the Court, the patent is revoked, and the patentees have been ordered to pay to the applicant the sum of 75 guineas in respect of his costs.

West Ham and the Local Government Board.—Mr. A. Hugh Seabrook, Engineer and Manager of the West Ham Corporation Electric Supply Department, writes us to correct a statement in our editorial note last week. The estimates for the loan, he says, were not revised as a consequence of any dispute between the Corporation and the Board, but owing to the fact that much of the work was completed and the actual cost known, enabling a reduction to be made in the amount applied for. Several new amounts were applied for, owing to further works being necessary.

THE NEW "EXCELLO" FLAME ARC LAMP

An improved form of the "Excello" flame arc lamp, with much longer hours of burning than the previous patterns, is being put on the market by the Union Electric Co. The new lamp, which is illustrated in Fig. 1, is provided with two pairs of carbons, for burning in succession. As each pair has a burning life of somewhat over 17 hours, the total number of hours that the lamp will work with one trimming is about 35. The feeding mechanism is very simple, in spite of the necessity for a change-over device which comes into operation when the first pair of carbons is nearly burnt out; and a low initial cost is one of the advantages claimed.

One of the difficulties associated with flame arc lamps for long burning hours is the prevention of the deposit of ash on the globe. Unless some special means is provided to prevent the formation of this

Fig. 1.—Lamp with Prismatic Inner Globe.

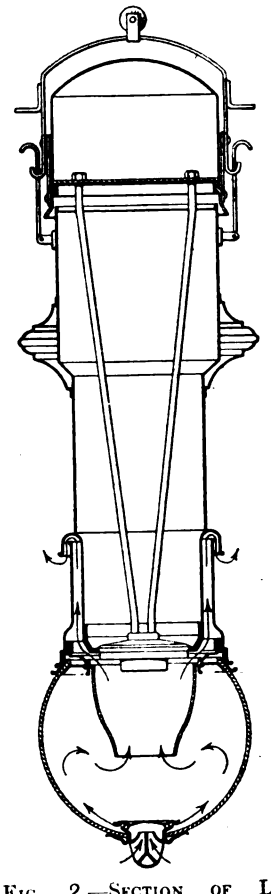

Fig. 2.—Section of Lamp with Plain Inner Globe.

deposit, the candle-power of the lamp gradually decreases, owing to the absorption by the clouded globe, which may amount to as much as 50 per cent. The new lamp is fitted with an inner chimney or globe as shown in Fig. 2, which induces a strong upward draught. Not only does this carry the fumes rapidly away, but as the globe is so close to the arc, it gets hot quickly, and this tends to prevent the formation of a deposit. The body of air between the globes prevents the cooling of the inner one. Another new feature is the ashtray, below which are several vertical, radial vanes, arranged to assist the upward draught of air and to act as an air-trap. The products of combustion are carried through the inner globe and between the cover and the inner sleeve of the lamp as shown in Fig. 2. A certain amount of ash is deposited on these metal surfaces, but this is easily wiped off when trimming the lamp. Actual tests have proved that after burning 100 hours, there is practically no deposit on either inner or outer globes. All the "Excello" lamps can now be obtained, fitted with inner globes, as well as the "Duplex" lamp.

The ordinary flame arc lamp with converging carbons gives its maximum illumination in a downward direction, and although this property makes it eminently

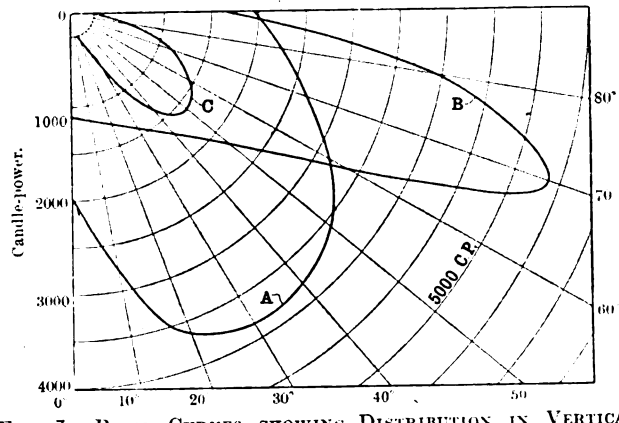

Fig. 3.—Polar Curves showing Distribution in Vertical Plane.

B. Flame arc lamp with prismatic inner globe.
C. Ordinary open vertical carbon arc lamp.

suitable for the illumination of shop-front and other similar purposes, it is a disadvantage in street lighting. In order to obtain a more general distribution from such lamps, the inner globe described above is provided with a number of prismatic ribs which can be seen in Fig. 1. The interior of the globe is quite smooth, the prisms being moulded on the external surface. The effect of these prisms is well shown by the polar curves of Fig. 3. Of these, curve *A* is the distribution curve obtained from an ordinary "Excello" 10-ampere flame arc lamp with clear glass globes, both inner and outer. The maximum illumination is obtained at an angle of 30° from the vertical. Curve *B* is the distribution obtained with the same lamp provided with a prismatic inner globe. The maximum illumination is obtained at an angle of 70° from the vertical in this case. For the sake of comparison, the distribution curve *C* of an ordinary 10-ampere, open, vertical carbon lamp is also given. In order to show the beneficial effect of the

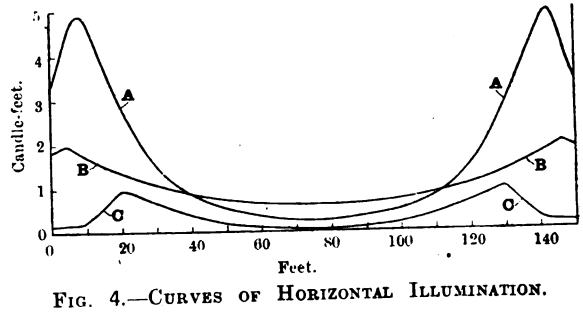

Fig. 4.—Curves of Horizontal Illumination.

A. Ordinary flame arc lamp.

C. Ordinary vertical carbon lamp.

prismatic globe when the lamp is used for street-lighting, corresponding curves are given in Fig. 4 showing the horizontal illumination at ground-level from lamps spaced 150 ft. apart and 25 ft. above the ground. It will be noticed that a much more uniform illumination is obtained by the use of the prismatic globe.

The mechanical design of the new "Duplex" lamp is similar to that of the standard "Excello" lamp, with

D

Digitized by Google

the exception of the feeding mechanism. The weighted carbons are supported by chains wound in opposite directions on drums, there being a drum for each pair of carbons. Each drum is geared through a train of wheels to an escapement-wheel. These wheels are shown at *A* and *B* in Fig. 5, which illustrates the

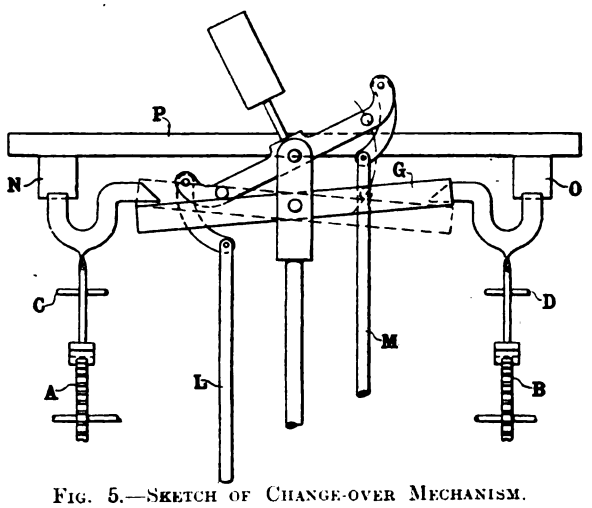

FIG. 5.—SKETCH OF CHANGE-OVER MECHANISM.

working of the change-over mechanism. In the position shown, the pair of carbons to which the wheel *A* belongs is burning, and the anchor of the escapement, which is pivoted at *C*, is free to work when the detent *N* rises. The anchor of the other wheel *B*, which is pivoted at *D*, cannot move, however, as, although the detent *O* rises with the detent *N*, the bar *G* engages with the upper portion of the anchor, and holds it. The bar *P* is controlled by the shunt and series solenoids in the usual manner, and when the shunt solenoid rocks it up, the escapement-wheel *A* is released, and feeding takes place.

When the first pair of carbons are nearly burnt out, a catch on one of the chains lifts the rod *L*, and tilts the bar *G* into the position shown dotted. The anchor of the escapement-wheel *B* is thus released, and feeding of the second pair of carbons will take place directly the arc on the first pair lengthens out. When the second two touch, the arc is transferred from the first pair to the new carbons. The arc is thus never extinguished, and the light given out by the lamp is practically unaffected during the change-over from the first to the second pair of carbons. After the second pair have been consumed, another catch rises and pushes the rod *M* up again, so that the first feeding mechanism is ready to operate as soon as the lamp has been supplied with fresh carbons. Attached to the bar *P* there is a rod which strikes and regulates the arc in the usual manner.

The economiser of the lamp is not divided into two compartments, as in some double-carbon lamps. It is of fireclay, and is held in an iron ring which forms part of the magnetic circuit of the "blow" magnet. The four carbons enter through four holes and are surrounded above the economiser by short brass tubes, in which they fit closely. By this means, the deposit of ash on the sides of the carbons is prevented. To ensure that the arc shall strike on the second pair of carbons, even if they are covered with a certain amount of ash, both carbons are put in with square, instead of pointed, ends.

The carbons used are the well-known "Excello" cored flame carbons, with a metal strip in the core to give better conductivity. When required, the lamps are fitted with a self-contained automatic cut-out and substitutional resistance. The pressure per lamp for series running is 46 volts. The overall length of the lamp is 3 ft. 9 in., and the maximum diameter of the case 12¾ in.

CATALOGUES AND PAMPHLETS RECEIVED

ELECTRIC RAILWAY MATERIAL.—A new group of price lists and leaflets covering a very extensive range of traction apparatus for both continuous-current and single-phase electric railways has been issued by Messrs. Siemens Bros. Dynamo Works, Ltd. A complete series of fittings for overhead lines for both the bow and trolley contact is included, those relating to the Siemens system of catenary suspension being contained in a separate list, in which the equipment of the Hamburg-Blankenese-Ohlsdorf Railway is illustrated as an example. Particular attention may be drawn in this section to an illustration of the automatic trolley wire tightener used on this line. Various forms of bow trolley and shoe contacts are dealt with, and a number of special designs of circuit-breakers, lightning arrestors, and motors for traction purposes, are listed. A feature of the controller catalogue is the completeness of the list of spare parts, and the same may be said of the section devoted to continuous-current traction motors. Perhaps the most interesting of the series of lists is that containing particulars of single-phase motor-car and locomotive equipments, including contactor gear for multiple unit operation.

MOTORS AND DYNAMOS.—A pamphlet from Messrs. Cutting Bros., Ltd., of Park Works, Stamford, gives particulars and prices of their standard lines of two- and four-pole motors and dynamos for continuous current. Shunt-wound motors from ¼ to 32-h.p. capacity, and generators with outputs of from ⅛ to 18 kw. are listed. Various patterns of frames are illustrated, and some general particulars relating to the construction, rating, and delivery of these machines are given in this pamphlet.

DRY CELLS.—Messrs. Siemens Bros. & Co., Ltd., of 12 Queen Anne's Gate, Westminster, London, have issued, as a supplement to their catalogue of dry cells, a leaflet containing particulars and prices of the new "Dura" cell, the chief feature of which is that it is delivered with the exciting agent in a dry and inactive condition, so that no action can take place before it is required for use. Plain water is added by the user to put the cell in an active condition. The E.M.F. of the cell is 1·5 volts, and the internal resistance varies between about 0·13 ohm. for the 8-lb. size, to about 0·5 ohm. for the ½-lb. size. Two brass terminals instead of the usual one terminal and wire connection can be had if required.

ELECTRO-MEDICAL APPARATUS.—To those interested in the application of electrical science to medical purposes, the new catalogue just issued by Messrs. Harry W. Cox, Ltd., of 47 Gray's Inn Road, London, W.C., cannot fail to be of value. Besides being a most complete and carefully arranged price list of all the various specialities manufactured and sold by the firm, it contains a large amount of information with regard to the management of electro-medical apparatus and to the application of electrical treatments. A list of books on the subject is included in the catalogue.

CALENDAR.—We have received a daily tear-off calendar from the Chloride Electrical Storage Co., a useful feature of which is the inclusion on each daily sheet of a small calendar for the current month, together with still smaller calendars of the preceding and forthcoming months.

DIESEL ENGINES.—We have received a catalogue from Messrs. Mirrlees, Bickerton, & Day, Ltd., of Hazel Grove, Stockport, giving full particulars of the British-made Mirrlees-Diesel engine of their manufacture. In general features these engines, one of which was shown at the recent Manchester Exhibition, are similar to the original forms of vertical four-stroke Diesel manufactured abroad; but a number of improvements in design have been effected as the result of experience with engines in actual service, among which may be mentioned the way in which removable valve seats are provided. The preliminary experimental work was carried out by the Mirrlees-Watson Co., and the new company formed to deal with this branch of their business took over the members of the staff experienced in Diesel engine work, and Mr. H. H. Bickerton, Chairman of the National Gas Engine Co., joined the Board. A particularly interesting type of engine is that used for electric lighting purposes on board warships of the *Dreadnought* and other classes using the same oil fuel as that employed for firing the boilers. These are four-cylinder enclosed short stroke engines of compact design, running at 400 r.p.m., and coupled directly to continuous-current dynamos. Diesel engines for marine propulsion are also illustrated.

The Electrical Football League.—Previously to last Saturday's matches the Metropolitan Electric headed the Electrical Football League, with a record of seven matches played and won. The County of London Electric came second with a similar number of matches played, but with one lost match. The remainder of the teams in the League came in the following order:—St. Pancras, seven matches played, three won, three lost, one drawn; St. James and Pall Mall, nine matches played, three won, four lost, two drawn; General Electric, eight matches played, two won, three lost, three drawn; Robertson's Lamps, seven matches played, two won, four lost, one drawn; Ediswan, nine matches played, eight lost, one drawn.

TESTING OF CONTINUOUS-CURRENT MACHINES

IN a Paper read before the Birmingham Local Section of the Institution of Electrical Engineers, on February 10th, Dr. W. Lulofs describes a method whereby the Kapp-Hopkinson or circulation-of-power test can be carried out on a single continuous-current machine, providing that it is lap-wound and is not supplied with equalising connections.

The principle, says the author, can be best understood from an inspection of Fig. 1, and is as follows:—The brushes are disconnected, and two ammeters, A_1 and A_2, of equal range, are inserted in the two negative leads, whilst the positive brushes are short-circuited through an ammeter A_3. Should now the exciting current of the south poles so be altered that S_{A_1} is strengthened by the same amount as S_{B_1} is weakened, then a difference of potential must be obtained between the two positive brushes when the armature rotates. This E.M.F. will give rise to currents in the two halves of the armature, and the directions of these currents will be such that the resultant armature ampere-turns produce a field which lies in the direction N_{B_1}, N_{A_1}, strengthening N_{B_1} by the same amount as N_{A_1} is weakened. The armature, however, revolves in this field, and for this reason a potential difference will be created between the two negative brushes. The armature ampere-turns corresponding to the currents consequent upon this E.M.F. will in turn excite a field over the two south poles in the direction S_{A_1}, S_{B_1}; that is, in the opposite direction to the alteration originally produced. Thus the armature reaction tends to prevent a circulating current from flowing from one brush to the other of equal potential. By altering the excitation of the north poles, however, the armature reaction can be balanced. A circulating current then leaves the positive brush under S_{B_1}, flows through A_3, and back to the brush under S_{A_1}, dividing equally in the two halves of the armature. The magnitude of this current is dependent on the alteration given to S_{A_1}, S_{B_1}, and the armature reaction produced by itself. When the armature reaction is properly balanced, the ammeters A_1 and A_2 will show equal deflection.

The machine can be started up in the ordinary way as a motor running light, and its speed can be adjusted by the voltage impressed on field or armature. A_1, A_2, and A_3 will all read half the running-light current, and the sum of A_1 and A_2 multiplied by the voltage impressed gives the power consumed exclusive of the field watts. The full load current can then be circulated in the armature winding by altering the excitation, and A_3 will read double the value of this current, plus or minus half the running-light current. The current divides in the armature as shown in Fig. 1. That part of the armature under the south pole S_{A_1} carries a current $\frac{1}{2}c+\frac{1}{2}d$ (where d represents the driving, and c the circulating current), and working under the stronger pole acts, therefore, as the motoring half. The opposite part carries $\frac{1}{2}c-\frac{1}{2}d$, *i.e.*, the smaller current, and acting under the smaller field works as dynamo. To take an actual full-load test, the excitation must be adjusted until the current registered by A_3 plus half the driving current is equal to the full-load current. The driving current is obtained from ammeters A_1 and A_2, each reading half this amount, and arranged to indicate equal currents by a suitable out-of-balance of the two north poles, N_{A_1}, N_{B_1}. In this way the armature reaction is counterbalanced, so that a circulating current can flow between the positive brushes only.

In order to calculate the true efficiency of a machine under working conditions from the figures obtained in this way, some corrections must be made, as two losses are not expressed in these results, namely, the negative brushes carry no circulating currents; secondly, the fluxes in the poles N_{A_1} and N_{B_1} are not distorted by the armature current flowing under them. These losses have to be added separately. To find the value of these additional losses, the measured no-load losses must be added to the calculated armature C^2R losses, and the sum subtracted from the corresponding figures found from the test, which will include half the brush and distortion losses. The result is the required half of the brush and distortion loss. The field losses can be readily measured. An error which cannot be corrected is that due to the rotation of the armature in a field superposed over that of the two poles N_{A_1} and N_{B_1}, but this is not appreciable. There is, due to this field, a slight side-pull on the shaft which might affect the friction losses, but as the friction losses do not depend on the bearing pressure unless the latter exceeds about 550 lb. per square inch, this is of no consequence, especially if care is taken that the stronger field is above.

A second method proposed by the author necessitates the employment of an auxiliary machine capable of carrying half the full-load current. In this case the difference of potential between the two positive brushes is obtained with the aid of the auxiliary machine, instead of by varying the excitation. It is still necessary, however, to alter the excitation of the two north poles in order to balance the armature reaction. The same conditions as in the previous method are obtained, but the brush and distortion losses are more easily separated. Neither of the above arrangements can be used for a temperature test, as it is not possible to correct for the additional losses.

A third method, however, is proposed by the author, and this consists in sending half the full-load current (C) through the armature from the auxiliary machine by way of the positive brushes as in the second method, and short-circuiting the negative brushes through an ammeter. The poles are normally excited, but current C exerts no torque. By varying the excitation of the south poles, and at the same time counterbalancing the armature reaction of C until the ammeter reads half the full-load current, the full-load running conditions are

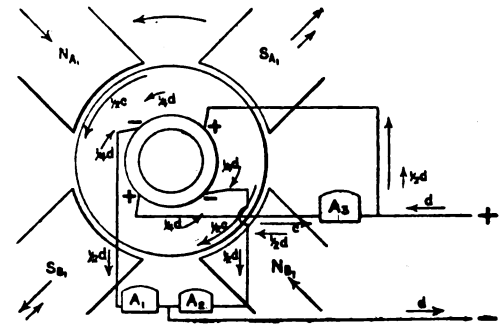

FIG. 1.—DIAGRAMMATIC REPRESENTATION OF AUTHOR'S TEST.

obtained, and the product of the voltage of the auxiliary machine and amperes C give at once the full-load loss. The only difference to the load condition is that in every other armature bar double the current flows, while the other bars are free from current. The average current carried by any bar is the full-load current, however. Values of the efficiency obtained by this and the first method for a four-pole, 230-volt, 120-amp. machine experimented with by the author agreed fairly well. The difference in the armature iron losses caused by the necessary unequal flux densities in the above methods are calculated by the author and shown to be negligible. A temperature test carried out on the above machine, according to the third method gave a maximum armature temperature rise, as calculated from the increase in armature resistance, of 23·9° C., whereas the maximum rise obtained by means of an ordinary Kapp-Hopkinson test, amounted to 24·5° C. Although the above tests are described for a four-pole machine, they can be adapted for any number of poles except two.

Finally, Dr. Lulofs deals generally with the effect of armature reaction in a lap-wound machine, which he says is not generally realised. If, he says, the armature of a four-pole lap-wound machine is eccentric and the air-gap under one north pole is smaller than under the other, a circulating current flows; but the armature reaction due to this current weakens one south pole and strengthens the other, and consequently a current will tend to flow whose magnetic action opposes and partly wipes out the original difference in strength between the two north poles. Again, as soon as the poles get saturated the actual difference due to eccentricity of the armature, or to any other reason, diminishes rapidly. These two facts explain why in a lap-wound machine the current divides fairly equally in the armature at all magnitudes of excitation, even when the armature is appreciably out of centre. The brush position and the direction of rotation have also a great influence.

The above effect can be applied to the design of a constant-current machine. This would be a four-pole machine; opposite poles would be of unlike polarity, and one pair of brushes would be short-circuited. The current through the short-circuited brushes would magnetise the poles corresponding to those brushes in such a manner that the resulting current in the armature would demagnetise the generating-field poles. By suitably exciting the former poles, however, a current can be taken from the brushes not short-circuited, which will be constant for varying speed, as, if the speed goes up or down, a balancing armature-current will flow through the short-circuited brushes, weakening or strengthening the generating-field respectively.

DISCUSSION.

Dr. W. E. SUMPNER (Birmingham Municipal Technical School), who opened the discussion, pointed out that the method described by the author required a considerable amount of thought in order to properly understand it, and before accepting it, prolonged tests on various types of machines were necessary. Any multipolar machine might be considered to contain a number of separate complete machines corresponding to the number of pairs of poles, and Dr. Lulofs virtually split up a four-pole machine into two separate machines, which he proceeded to test on the Kapp-Hopkinson method.

Mr. S. H. HOLDEN (Messrs. Chamberlain & Hookham) asked whether there was not a possibility of the commutation being affected by short-circuit currents between the segments under the brushes, owing to the variation in the strength of the field. He suggested that the bearing friction would be changed by altering the magnetic pull, and would not have the proper value when the magnetic pull was arranged in an upward direction, since this would alter the pressure on the bearings from what it would be under normal conditions.

Dr. G. KAPP (Birmingham University) questioned whether designers were not wrong in assuming that the circulating currents were dangerous, and thought it probable that equalising connections were unnecessary.

Mr. A. E. GOTT was glad to learn that there was no difficulty in applying the method to a machine with an odd number of pairs of poles. He pointed out the fact that all the weakened poles were on one side of the armature, and that there would therefore be a large strain, due to the unbalanced magnetic pulls; although motor shafts were made fairly rigid, they might not stand this strain.

Dr. J. D. COALES (Birmingham University) was of opinion that the circulating currents were not of any considerable size, as it was evident from the results of the author's experiments that the currents in the two halves of the armature did not differ greatly in value. It was a very difficult matter to accurately measure the resistance of an armature, including the brushes, when the machine was running.

Mr. G. A. WIGLEY (Messrs. Tangyes), in a written communication, regretted that the method was not applicable to a two-pole machine, to a series or wave-wound machine, or to one with equalising connections. Manufacturers generally employed wave-windings for small machines whenever possible, on account of the superior slot space-factor, the elimination of troubles due to unequal pole-strengths and the possibility of using only two sets of brushes, although sometimes the latter advantage was sacrificed when the number of brush sets fitted was made equal to the number of poles, in order to reduce the length and cost of the commutator. Again, equalising rings were nearly always fitted to parallel or lap-wound armatures, especially now that the general use of special commutating poles had raised the sparking limit and made the heating limit relatively more important. It would be interesting to know whether the author could adapt his method to meet these cases.

Dr. LULOFS, in reply, stated that while he agreed with Dr. Sumpner that it was not at all an easy matter to grasp the working of this method of test, he thought that it was not more complicated than many methods in use at present. He considered that in the case of a machine in a power station, when it was a question of whether the conditions of a specification had been met, his system, by obviating the necessity for procuring two machines of the same size, in order to carry out a Kapp-Hopkinson test, would be a great convenience. As regards Dr. Sumpner's criticism of his definition of a machine, he had always been under the impression that a machine consisted of a piece of apparatus with one shaft, one armature, and one field. As regards the magnetic pull, this could be calculated and could be so arranged as to produce a pressure on the bearing equal to that under normal conditions, though not in the same direction. The cause of circulating currents was the high saturation of the fields generally adopted, and designers should be able to avoid the necessity for equalising connections by a more suitable design. It was possible that the commutation might be injuriously affected by the alteration of the poles, but the alteration was not of great amount.

ELECTROMETALLURGY AND ELECTRO-CHEMISTRY

THE electrolytic detinning of tin scrap has been in operation for some time, and very large quantities of scrap are annually treated. There is not much patent literature upon the subject, as most of the works preferred to operate as secretly as possible. In *Stahl und Eisen*, of December 30th, 1908, there is an interesting article by Dr. Karl Goldschmidt. The firm of Theodor Goldschmidt commenced to work at the problem of detinning tin scrap as far back as 1882. The scrap was placed in wire baskets, and made the anode in a hot solution of sodium hydroxide. In the laboratory, on a small scale, the process was fairly simple; but it was quite another thing to operate satisfactorily on a commercial scale.

When the electric current was passed the tin at the anode passed into solution as sodium stannate, and at the cathode it was deposited. For the dissolving action to take place the presence of free caustic soda was necessary. The atmospheric carbon dioxide, however, gradually converted it into carbonate, and the lifting out of the anodes and cathodes removed considerable quantities of the electrolyte, which, of course, also contained tin. In order that the electrolyte should satisfactorily attack the scrap, it could not be compressed to any extent, otherwise it would not become wetted. The consequence was that each anode basket could only hold from 10 to 20 kilogram of scrap. This meant a high cost for labour and also a large amount of vat room. The surface of the tin treated at the Goldschmidt works in Essen a day is rather over 12 acres, consequently the labour is a serious item, and the loss of electrolyte simply to wet this large quantity of scrap is considerable. If to recover this the tin is washed, the solution is too dilute to be of much value, and does not repay the trouble of working it up. The tin is deposited on the cathodes in a spongy condition, and is purified by melting it down, when it assays 97 to 98 per cent. The iron remaining is melted down in an open hearth furnace, and is of good quality.

Dr. Goldschmidt has now introduced a chlorine process of detinning, which has for some time been working side by side with the electrolytic process, and is found more satisfactory. Although the chlorine process is not electrolytic, yet it entails electrolytic chlorine, that is to say, the electrolysis of a sodium chloride solution, with the production of caustic soda and chlorine. It is necessary to have the chlorine very dry and the tin also. The scrap is then placed in a tower after having been compressed into bundles, and chlorine gas is forced into it. It is necessary to force it in under pressure, so that it may penetrate into all the interstices. Considerable heat is produced, and the tin tetrachloride formed distils over—it is largely used in silk works. One great difficulty at first met with was the rapid manner in which the iron rusted after the tin had been removed from it. This was ultimately found to be due to the presence of a very thin film of ferric chloride. The ferric chloride then absorbed moisture from the air, and so caused the rusting. By washing the iron after it has been treated with chlorine the ferric chloride is removed, and the iron does not then rust. It should be mentioned that the tin scrap treated is cuttings obtained in the manufacture of tinned boxes, &c. Old tin cans and so on could not very well be treated by the electrolytic process, but it is found possible to treat them after a preliminary purification by means of the chlorine process. The total amount of tin recovered from tin scrap in the United States and Europe is from 3,000 to 3,500 tons per annum, and the weight of iron about 75,000 tons.

Dr. G. Erlwein and Viktor Engelhardt have patented the production of calcium carbide in the induction furnace (*German Patent* 206,175). In order to heat the charge, which consists of limestone and coke, a ring of liquid carbide is first poured in. Or a carbon ring, which will itself react with the carbide mixture, is put into the induction ring. It is claimed that by using an induction furnace for the production of carbide in place of an electrode furnace the loss of heat by radiation is less, and the electrical energy is more completely employd in the reaction.

ELECTRIC COFFEE ROASTER

A NEW pattern of coffee-roaster is now being manufactured by the Phœnix Electric Heating Co., Ltd. It consists of two cylinders of perforated steel, the inner of which contains a stationary heating element. The coffee beans are placed in the annular space between the cylinders, and the outer one is rotated. Helical blades are arranged in the space between the cylinders to ensure that the beans are well mixed and uniformly roasted. The company has a large roaster at their showrooms capable of dealing with seven pounds of beans at a time, and taking 4 watts. Starting up from the cold state, the single charge of seven pounds is roasted in twelve minutes. Therefore, at a charge of 1d. per unit, the cost of the energy for roasting works out at about ½d. per pound. When once hot, a second charge can be roasted in ten minutes. The heating element consists of several spirals of non-oxidising resistance wire, which is run at a bright red heat. The spirals are fixed to porcelain or fire-clay insulators mounted on a steel frame. A very even roast is obtained with this apparatus, and it is claimed that a better flavour than that from gas-roasted beans is produced. In order to see when the beans are roasted to the requisite amount, an ingenious contrivance is fixed to the rotating cylinder. This consists of a cup which picks up three of four beans and throws them out of a small opening in one end of the cylinder when a knob at the side is depressed. It is thus unnecessary to stop the cylinder or open it in order to sample the beans.

Faraday House.—On Tuesday Mr. Robert Hammond commenced a short course of lectures to the students of Faraday House (third year, intermediate, and senior term) upon "Electrical Legislation."

ELECTRIC CRANE EQUIPMENT AT TRANMERE BAY, BIRKENHEAD

An important electric crane equipment has been installed by the Tranmere Bay Development Company (Limited) at their new graving docks and shipyards on the Birkenhead side of the River Mersey. In the accompanying illustrations are shown the two most interesting types of cranes, which are now in working at this establishment, both of which were constructed and erected by Messrs. Bechem & Keetman (Duisburger Maschinenbau Actiengesellschaft), of Duisburg. Figs. 1 and 2 illustrate an interesting type of fixed "hammer" derricking crane of 150 tons lifting capacity. With this crane there are four motors arranged to work on both 440 and 220 volt direct current, divided as follows:

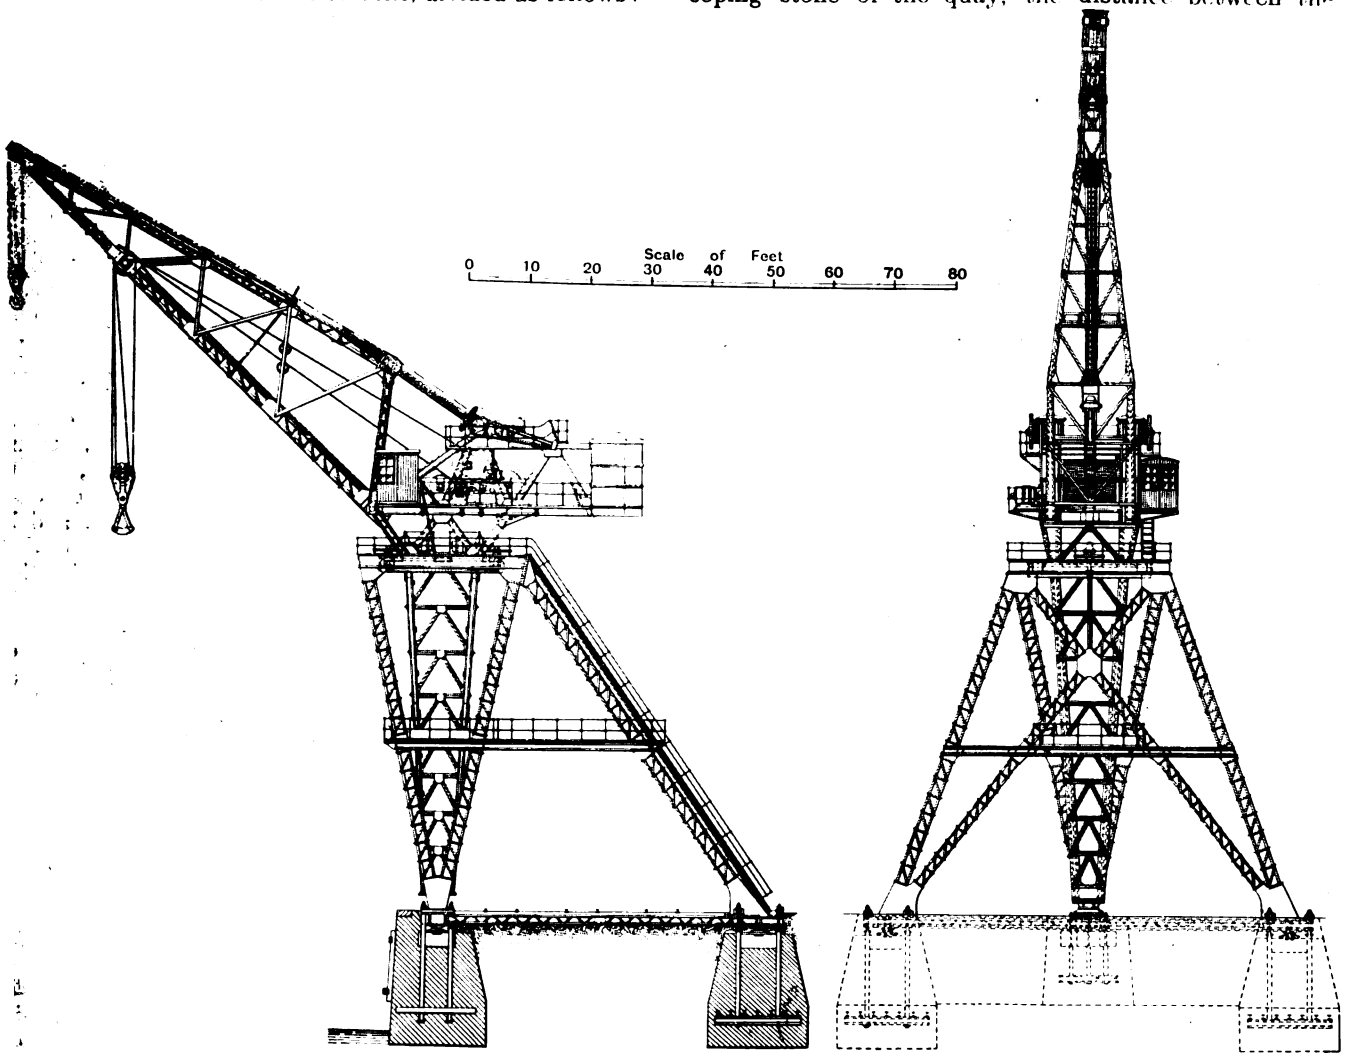

Fig. 1.—Elevations of 150-ton Fixed "Hammer" Type Four-Motor Crane.

(1) For the lifting gear, one motor of 110 h.p., at about 480 revs. per minute; (2) for the revolving gear, two motors each of about 12½ h.p., at about 400 revs. per minute; and (3) for the luffing gear, one motor of about 57 h.p., at about 500 revs. per minute. The working speeds attained are: Lifting of the load of 150 tons, about 5 ft. per minute; lifting of the unloaded large hook, about 8·3 ft. per minute; lifting of the load of 50 tons at the small hook, about 20 ft. per minute; lifting of the unloaded small hook, about 33 ft. per minute; turning one complete revolution of 360° in 5 to 7 minutes; luffing of the jib from the largest to the smallest outreach, with the load of 150 tons attached to the hook, 10 to 15 minutes. Consequent upon the series-wound direct-current motors in automatically increasing their revolutions at the decreasing load, the speeds fixed for working with the maximum become greater when smaller loads are being dealt with. The crane has a movable jib, the top of which copes with a working field lying between two concentrical circles of 280 ft. and 89 ft. The top hook is used for lifting loads of 50 tons, and the lower one loads up to 150 tons. The greatest height of the upper jib pulley of the 50 tons lifting gear is about 114·10 ft. The distance from the middle of the hook at its highest position to the middle of the jib pulley is 110 ft. 6 in. for the 50 tons lifting mechanism, and 118 ft. for the 150 tons lifting gear. The 150 tons load can be lifted at an outreach of 46 ft. from the outer edge of the coping stone of the quay, the distance between the axis of the front legs of the supporting frame and the coping stone of the quay being about 65 ft. 1 in. At this radius the distance between the lower edge of the 150 tons hooks at the lowest position and the middle of the jib pulley is 113 ft. A radius of 65 ft. above the coping stone of the quay for the 50 tons hook corresponds with this position of the jib. The largest outreach at which dead loads of 50 tons may be lifted is 82 ft. above the coping stone of the quay. Material with a diameter up to 6 m. can be taken up and loaded by the crane from the middle railroad. The crane consists of a stationary supporting frame having three legs, and of the movable part revolving round a complete circle. The upper platform of the supporting frame serves as pressure ring, and shows a circular section in which the turning part of the crane is guided. The latter consists of the centre column having a

Digitized by Google

slightly tapered shape towards its lower end of the large main platform, carrying the gearings and the box for the counterweight, and of the jib added to this platform. The weight of the turntable part of the crane is, as previously remarked, taken up by the centre

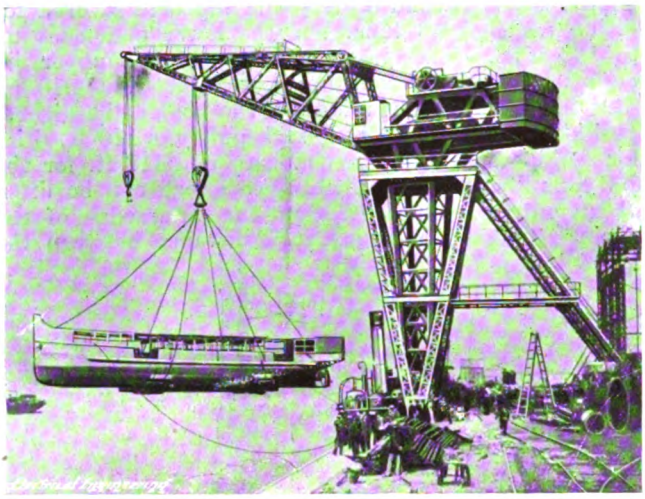

FIG. 2.—GENERAL VIEW OF 150-TON CRANE.

foundation. Furthermore, the revolving portion of the crane produces a tipping moment, manifesting itself in two horizontal forces, one of which acts at the foot of the column, and the other at the pressure ring. In order to take up the forces acting upon the centre foundation, a combined step and collar bearing is arranged on the same, having amply sized sliding surfaces, which work constantly in oil. The connection between the column and the bearing is such that, even should the foundations settle a little in a one-sided manner, or the crane sink a little, detrimental consequences for the bearing surfaces of the crane are obviated. Further, the bearing is protected in the most suitable manner against the intrusion of dirt and moisture by means of the oil-box covering. The upper horizontal tension in the pressure ring of the supporting frame is compensated by a roller collar bearing. At the turntable column there are fixed six pressure rollers running against a bent rail, fastened to the inside of the pressure ring mentioned. In the designing of the iron construction it was taken into consideration that each portion is accessible for renewing the painting, and to prevent the gathering of water. The two lifting gears are placed on the main platform of the turntable part of the crane, and driven by the same lifting motor alternatively. The gearing for the 50 tons lifting mechanism is placed aft. The load is suspended by six strands of rope, two of which are simultaneously engaged, and coiled round two drums alongside of each other. The gearing for the 150 tons load is placed forward, and has two rope drums situated behind each other, each of them winding up one fall of the lifting rope, the ply pulley being suspended by ten strands of rope. All the reductions between the motor and the drums of the two lifting mechanisms are brought about entirely by spur wheels. The coupling of the two lifting gears is effected in a simple way by means of a hand wheel. Powerful hand brakes are used for arresting the load, and the driving gears when uncoupled. The hooks for the loads are mounted upon balls, and turn easily. The revolving gear of the crane consists of two equal driving devices, each driven by a separate motor. The reduction is effected by worm gearings and spur wheels transmitting the motion upon two toothed pinions, which act upon a driving rack fitted at the pressure ring. The driving rack is made of sectional steel, and the teeth consist of turned steel bolts, which, in the event of wear, can easily be replaced. The winding gear for adjusting the outreach of the jib, *i.e.*, the luffing gear, is arranged above the lifting mechanism. Two powerful steel spindles screw themselves into two nuts of manganese bronze, fixed in the jib. The nuts, as well as the lower ends of the spindles, rest in cross-bearing traverses, which pivot around horizontal axes. The two spindles are fitted with bevel wheels, which mesh with counter wheels placed upon the turning pivots of the respective traverses. Further reductions between this and the motor are effected by spur wheels. The spindles are provided with counteracting turning movement. In order to guarantee an exact operating with the jib, the spindles are provided with a hand brake, electro-magnetically worked. The current is directed to slip rings, which are placed close above the lower platform arranged halfway up the supporting frame, and from here is conducted to the main switchboard at the attendant's house, where a quick main switch, as well as the double pole fuses for all circuits, are located. The outreach of the jib at any position can be read by the driver from an indicator worked by the jib. The electrical equipment was supplied by the Siemens-Schuckert-Werke of Berlin. The motors are series-wound, and are all enclosed so as to be dust and waterproof. The larger toothed wheels, as well as the pressure rollers, are made of the best malleable cast steel. The quicker running wheels, generally the first and second reduction gears, are provided with machine-cut teeth. The small pinions, the spindles, all the axles and shafts, are made of wrought steel, whilst the worms for the revolving gear are manufactured of best tool steel. The worm wheels have a cast core, around which a ring or collar of best bronze is shrunk, and in which the teeth are cut in due course. The ropes consist of wires of the best crucible cast steel, and in order to lengthen their life they are so arranged that they run over the pulleys and drums in one direction only, and the diameter of the latter is at least twenty times greater than that of the rope diameter.

The portal crane illustrated in Fig. 3 is capable of hoisting, lowering, and swinging a load of 40 tons at an outreach of 78 ft., and of travelling under a full load at a speed of 39 ft. 5 in. per minute. The following

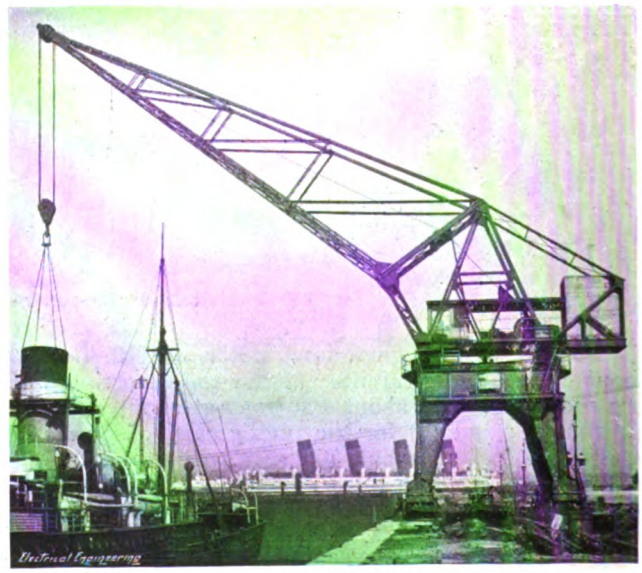

FIG. 3.—40-TON PORTAL CRANE.

are the working speeds:—Lifting up to 10 tons, 41 ft. 6 in. per minute, with a motor of 50 h.p., running at 525 revs.; lifting up to 40 tons, about 10 ft. 4 in. per minute. Turning, about 197 ft. per minute, measured at the hook, with a motor of 33 h.p. running at 675 revs. Travelling, about 39 ft. 5 in. per minute,

Digitized by Google

with a motor of 33 h.p., running at 675 revs. The distance between the centre of the upper jib pulley and the lowest position of the hook is 128 ft. 6 in., and the distance between the centre of the upper jib pulley and the upper edge of the quay is 82 ft. The rail gauge of the main carriage is 23 ft.; the wheel-base of the crane is 29 ft. 6 in.; the gauge of the carriages under the crane pedestals is 4 ft. 8½ in., and the wheel-base of the carriages under the crane pedestals is 5 ft. 9 in.

THE ELECTRIC WINDER AT THE GREAT WESTERN COLLIERY CO.'S MARITIME PIT

A PAPER was read by Mr. G. Hooghwinkel last month before the South Wales Institute of Engineers on the electrical main shaft winding equipment which has been installed at the Great Western Colliery Co.'s Maritime Pit, near Cardiff. The Paper commenced with some introductory remarks on electric and steam winding.

The winder in question was required to wind 175 tons of coal per hour from a depth of 1,110 ft. in 70 winds, giving 5·6 tons of coal per wind in two trams. When the plant was projected, the main point at issue was whether the Ilgner equaliser plant or the Westinghouse system should be adopted, and the main point which decided the management to adopt the Westinghouse system was that in this system a three-phase motor is used capable of being run direct from the mains. The absence of recuperative power with this system was met by the ingeniously designed drum which, if properly handled, stops without any braking being required after the current is cut off.

The Westinghouse system, in which the flywheel set only deals with the differences between the maximum and the normal load, and therefore not only uses a much smaller flywheel, and can also still be employed to a reduced extent even in case of a total breakdown of the equaliser set, was fully described in Electrical Engineering, Vol. I., p. 125.

In the installation under consideration, the plant consists of the following items:—Winding-motor, normal rating 700 h.p. at 2,200 volts, 25 cycles, 56 r.p.m. Efficiency 90 per cent., 90 per cent., 91 per cent., at one-half, three-quarters, and full-load respectively.

Rotary converter, normal rating, 400 kw., three-phase, 550 volts, D.C., 500 r.p.m. Efficiency 87 per cent., 92½ per cent., and 94 per cent., capable of taking 100 per cent. overload during one hour.

Transformer, 400 kw., 2,200–350 volts. Efficiency 96·9 per cent., 97 per cent., and 97½ per cent., capable of 100 per cent. overload.

Flywheel machine, 250 kw., 550 volts, 500–750 r.p.m., coupled to flywheel of 24,000 lb., 6 ft. 1 in. in diameter, and 3 ft. 6 in. wide. Efficiency respectively 92 per cent., 93 per cent., and 95½ per cent. The winding motor and drum, the equalising set, and an exterior view of the winding-engine house and pit-head gear are shown in Figs. 1, 2, and 3, which bring out clearly the cleanliness and compactness of electrical winding machines as compared with steam plant as usually seen.

The controlling gear consists of:—

A liquid-starter combined with a three-pole reversing switch suitable for starting, reversing, and regulating the winding-motor. This starter is of special type, consisting of two large tanks, one of which contains the blades, while the other one serves as a reservoir for the liquid. The two tanks are fixed one upon the other, both being connected by inlet and outlet pipes, and the water is forced by an electrically-driven centrifugal pump from the lower to the higher tank, circulating continually between the two. An overflow is provided in the upper tank, which, if raised, causes the liquid to rise, so that by means of it the level of the same can be adjusted. The arrangement is such that even with the lowest level the blades are in contact with the liquid. The overflow is mechanically connected to the reversing switch and to the main lever on the driver's platform. In order to counteract the heat effect of the energy which is being dissipated in the liquid resistance, the lower tank is provided with a coil of cooling-tubes through which cold water may be run.

Fig. 1.—Winding-engine House and Pit-head Gear.

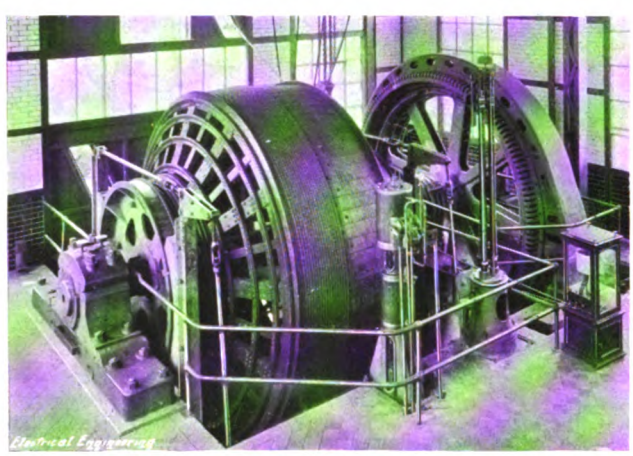

Fig. 2.—Winding-motor and Drum.

A three-phase, oil-immersed emergency switch, suitable to break 400 amperes at 2,200 volts is also provided. It is fitted with electrical and mechanical overload release, and trip gear for connecting to the depth indicator, the emergency brake lever and the no-voltage release magnet. A three-phase no-voltage release magnet is connected to the secondary of a transformer whose primary is connected to the main H.T. circuit. This magnet is mechanically connected to the emergency switch, and acts as a minimum release in case of no voltage, or in case the voltage drops below a certain minimum. A 12-kw. three-phase 2,200–220-volts transformer is also provided for supplying the brake magnet, the motor driving the centrifugal pump of the liquid starter, and also the 3 h.p. air-compressor motor.

The brakes which are linked to the drum are operated by compressed air, or, in emergency, by a weighted lever. The whole control gear is operated by means of three levers, which are fixed on the driver's platform. One lever serves for actuating the primary reversing switch and the liquid rheostat. The action of the liquid starter is such that the acceleration is automatic and quite independent of the speed with which the operating handle is operated. The action of the lever is such that first the primary switch is actuated and then the liquid starter. If the lever is moved to an intermediate position, the primary switch is being operated as previously described, while the liquid starter only moves into a position corresponding to that of the handle. In this manner the speed of the winding-engine can be varied within any limits up to full speed. The design of the control gear is such that counter current can be given to the motor when lowering if necessary. The second lever on the left-hand side of the driver operates the power brake. The third lever, which is in a central position, is only operated by the driver in case of emergency, and operates the release of the weighted end of the brake lever through a tripping device, and also brings the emergency switch to the "off" position by means of rods and links, thus interrupting the circuit of the motor.

The same action is obtained, but automatically, in the following manner:—The tripping mechanism of the emergency brake lever is connected mechanically to the depth indicator by means of rods and links, so that the emergency brake can be tripped at the end of the travel in case of overwinding; the emergency switch being operated at the same time through suitable links,

Digitized by Google

also by the releasing of the gear by a solenoid (which occurs in case the line voltage drops below a certain limit).

The control gear for the load equalising set and flywheel machine automatic field regulator for automatically regulating the voltage of the machine by varying the resistance in the field circuit consists of the following parts:—The automatic regulator is of the liquid type, and consists of an earthenware tank filled with diluted sulphuric acid. It contains two electrodes, one of which is fixed, and the other attached to a movable rod, the motion of which is controlled by a simple three-phase magnet. This magnet receives energy from the secondary of a three-phase transformer. The primary of the three-phase series transformer is connected in series to the H.T. three-phase circuit, the

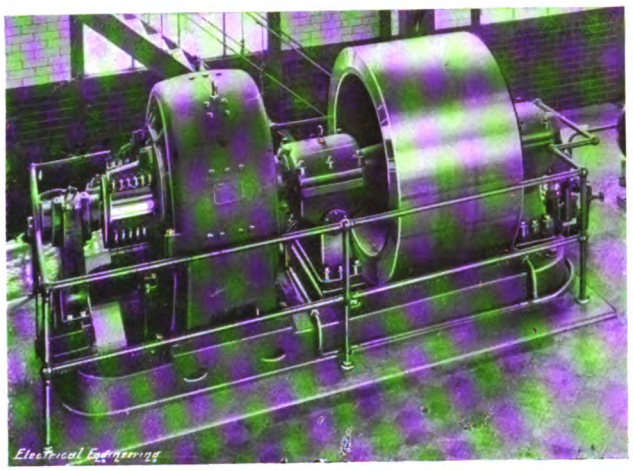

FIG. 3.—FLYWHEEL EQUALISER.

secondary supplying energy to the automatic regulator. A standard triple-pole switch of about 100 amperes capacity is provided for short-circuiting the motor magnet. The field rheostat for hand operating has about 80 contacts. A liquid starter is used for the D.C. flywheel machine.

The rotary converter on its D.C. side is connected to the D.C. flywheel machine, and delivers automatically the magnetising currents which are consumed by the induction (winding) motor. The voltage of the flywheel machine is controlled by a quick-acting regulating apparatus from the H.T. transmission line through series transformers. The operation is automatic, so that the converter equaliser discharges its energy into the H.T. system whenever the load is higher than the constant station output, and its stores energy in the flywheel when the power demand in the H.T. supply system is less than the constant output of the station. At no-load the rotary converter is acting at 100 per cent. power factor, giving the total constant capacity into the flywheel until it has come to its maximum speed. The capacity of the flywheel is taken large enough in order to take care of the overload and underload periods of the winding motor.

The principal points of the system to which attention may be called are the following:—The equaliser only transforms that amount of energy into direct current and back into three-phase current which is *above* and *below* the constant output of the station. The main winding motor is three-phase, and can be run direct from the mains, with a reduced output, if necessary. With light loads the equaliser may be shut down. One equalising set can take care of the power fluctuations of several winding engines, or other variable and intermittent electrical plant. During long pauses the equaliser can be shut down, because when restarting the light flywheel does not require much power (100 per cent. power factor). The compounded rotary equalises the wattless load on the station by giving magnetising current into the mains whenever they are required by other induction motors. The flywheel slip is not limited by the reduced efficiency, and can be varied from 30 to 40 per cent. without increasing the losses in the machine. This, of course, reduces the weight of the flywheel, the corresponding losses, and also does away with the difficulties of transport. The running of the D.C. machine is sparkless, as the overloads are commutated with a field which is increased with the slip; the smallest field corresponds with the highest speed, and therefore high-speed machines can be used giving maximum efficiency and minimum cost. No separate excitation motor generator is required. The equaliser set can be placed in the power station, or any other convenient place.

Test results have shown a consumption of energy of 1·995 units per ton of coal wound, or 4·98 units per trip, with 2·5 tons of coal. The number of units consumed per hour is therefore 348, slightly in excess of the guaranteed figure of 341 units, but within the allowed margin of 351 units.

The trams not being fully loaded and carrying only 2·35 tons of coal accounts for this small difference. Moreover, the conditions were not in favour of the tests, this being the first time full-load has been required from the engine and drivers.

THE MANCHESTER ELECTRICAL EXHIBITION

WE are informed that at a meeting of the Executive Committee of the Manchester Electrical Exhibition, held in Manchester on February 16th, it was agreed that 20 per cent. on the amount paid for space should be returned to the exhibitors, and that 10 per cent. on the sums granted by the various Corporations and District Councils should be returned to them out of the profits of the Exhibition. The balance remaining will be dealt with when the accounts are closed. A portion will be allocated to the charities connected with the electrical industry, and a portion to a charitable institution nominated by the Manchester and Salford Corporations.

It is of interest to recall that as the result of the Olympia Electrical Exhibition in London in 1905, 25 per cent. of the amount paid for space was returned to the exhibitors, the sum of £250 was handed over to the Benevolent Fund of the Institution of Electrical Engineers; and a contribution of £650 was made to the Electrical Trades Benevolent Institution. It may be pointed out that it would not be fair to make too close a comparison between the results in London and those in Manchester, for at the latter it was necessary to erect special buildings for holding the exhibition.

The Territorial Army.—Messrs. Veritys, Ltd., inform us that they are granting an extra week's holiday, in addition to the time required for training, to members of their various staffs who also belong to the Home Guards. A large number of this firm's employees at their works at Aston, Birmingham, have joined the three Southern Telegraph Companies R.E. (Army Troops), commanded by Lieut.-Colonel J. F. Lister, who is a director of Veritys, Ltd.

Electric Furnace for Tool Manufacture.—An electrically-heated furnace for use in conjunction with a Bradbury drill forging and shaping machine, is being constructed by the Phœnix Electric Heating Co., Ltd. The furnace is for use some thousand feet below the surface in one of the Rand mines. It is stated that an electric furnace has been chosen, as all other types would have been unsuitable in such a position, on account of the fumes emitted. The furnace is constructed in the form of a large number of heating units, each of which holds one tool only. Each unit comprises a fire-clay muffle, wound with special non-oxidising wire, and surrounded with a packing of slag wool, the whole being enclosed in a steel case. The internal diameter of the muffle is 2 in., and the length 2⅝ in. A cast-iron extension to the muffle holds the round end of the tool. All the units are mounted together on a steel framework together with the necessary switches and fuses. A battery of nine units takes a current of 25 amperes at 220 volts, or approximately 600 watts per unit. Some larger furnaces of similar design have also been constructed by the Company.

Large Country-house Installation.—One of the Scottish mansions of the Marquis of Bute, Dumfries House, in Ayrshire, is to be equipped with electric light and power. A farm and the adjacent buildings are also included in the scheme. The undertaking will comprise the installation of a 40 b.h.p. two-cylinder Diesel engine, running on shale or Texas oil, direct-coupled to a B.T.-H. dynamo-booster set. A storage battery of 56 Tudor cells will be installed, with a capacity of 970 ampere-hours, and provided with end regulating cells switched in automatically by a Bertram Thomas regulator (ELECTRICAL ENGINEERING, Vol. IV., Exhibit. Supplem., p. 28) fitted on the main switchboard. Over 800 105-volt metal-filament lamps and several motors will be connected. The wiring will be carried out with solid-drawn steel conduit except at ceiling fitting points, where flexible steel tubing with brass screwed connectors of special design will be used to facilitate exact adjustment of the joint boxes for flexible conductors to convenient positions above small holes bored in the decorated ceilings, and also at certain points for carrying main and sub-main cables. The underground mains insulated by vulcanised bitumen will be laid in haskinised wood troughing, filled in with plastic bitumen, and covered with tiles. The work is being carried out by Messrs. T. M. Mackay & Co., to the designs of Messrs. James E. Sayers and Caldwell, Consulting Engineers, of Glasgow, who have recently completed a water-power installation at Mochrum Castle, another of the Marquis of Bute's mansions.

RAILWAY ELECTRIFICATION

A PAPER on railway electrification was read last Thursday before the Rugby Engineering Society by Mr. F. W. Carter, of the British Thomson-Houston Co. The particular objects of the Paper were to compare the different systems of operation, to show that no one system satisfies all the needs of railway work, and to indicate the class of work to which particular systems are best suited.

Whatever system is adopted, said the author, a very large outlay has to be faced, and no case for electrification can be made out unless an increase in net receipts can be secured sufficient to more than pay interest on the extra capital involved. This increase may be brought about either by decreasing the working expenses for the same service, or by so modifying the service as to bring in greater revenue, or by a combination of these. In this country, where coal is cheap and little water power is available, the decrease in working expenses alone will not in general justify electrification. The question of the movement of trains is, in the main, a dynamical one, and the energy consumption is entirely determined by such considerations as type of train, distance between stations, and average speed. By assuming different groups of values of the above, it is possible to derive from mechanical considerations alone the necessary energy output of the train motors to accomplish any given schedule. Several cases were worked through by the author, and the results of his calculations were given in tabular form. These results show, as the author pointed out, that, other things being equal, the higher the rate of acceleration the lower is the energy consumption. The inequality, however, becomes less the greater the distance between stops; for whilst for a ¾-mile run the change from acceleration at 1 m.p.h. per sec. to acceleration at 0·5 m.p.h. per sec. increases the energy consumption under the particular conditions chosen by 50 per cent.—assuming the same weight of train—for a five-mile run, the increase is only 9 per cent. Since, however, in general, more driving machinery is necessary the higher the rate of acceleration—whereby the weight of the train is increased—the advantage in favour of a high rate of acceleration is reduced, since the energy consumption per train-mile is proportional to the weight of the train. Nevertheless a high rate of acceleration is essential in services where high average speeds are necessary over short lengths of run.

It is considerations of this nature, continued the author, which render the single-phase system unsuitable for urban service, where a high rate of acceleration is a necessity. The new trains of the London, Brighton and South Coast Railway carry eight single-phase motors for each three-coach train. The Metropolitan District Railway uses six continuous-current motors for a seven-coach train; and the motors in the two cases are of approximately equal weights. Had the Metropolitan District Railway adopted the single-phase system, the trains would have been at least 30 per cent. heavier, their energy consumption being increased in like proportion. It is probable that a half of the expense of electrification on this railway is represented by train equipments, and this item would have been more than doubled had the single-phase system been adopted. Apart from the greater capital outlay and energy consumption, the maintenance of the train equipments would have been much more expensive. Mr. W. S. Murray, the electrical engineer of the New York, New Haven, and Hartford Railroad, gives the figure of 1·5d. per mile for the maintenance of the 1,000 h.p. locomotives used on this line. This may be compared with 0·85d. per mile for maintenance for the 2,200 h.p. New York Central and Hudson River Railroad locomotives (average for 25,000 miles service) and 0·24d. per mile for the Buffalo and Lockport locomotives, which carry a 600 h.p. equipment (average for 132,000 miles service). It would appear from this that the maintenance of single-phase equipments is quite three times as expensive as that of continuous-current equipments of equal power. The determining factors are therefore all in favour of the continuous-current system for speedy and frequent urban or suburban service. The true place of the single-phase system is in somewhat infrequent inter-urban service. In such service, the rate of acceleration is of small consequence, the maximum speed being the determining factor in meeting the schedule. When trains are few for the mileage of track, it is desirable to feed as great a mileage as possible from each sub-station, and this is practicable with a single-phase system if a high voltage is employed. The Midland Railway Company's Heysham, Morecambe, and Lancaster service may be instanced as one quite suitable for single-phase operation. Here the distance between stations is several miles, the trains are infrequent, and the schedule speed is not excessive. The rate of acceleration that has been chosen, although low, is quite suited to the system and service, so that the driving machinery per train is moderate in amount.

Electrical operation as compared with steam shows to greatest advantage in urban and suburban service. Here, if multiple unit trains are employed so that a considerable fraction of the total weight is carried on driving wheels, thus permitting a high rate of acceleration to be used, a schedule speed quite impracticable in steam operation can be maintained. Moreover, a more frequent service can be given without a proportionate increase in expense. The operating costs are considerably reduced, and this saving alone should more than provide for interest on the extra capital. In the Manhattan Elevated Railway electrification, the last year of operation entirely by steam (1901) gave for total operating cost, including power, maintenance of equipments, permanent way and structures, with traffic and general expenses, 6d. per car-mile, whilst the first year of operation entirely by electricity (1904) gave 4¾d. per car-mile for the same expenses. In inter-urban service with several miles between stops, electrical operation does not offer the advantage of practically permitting a schedule speed in excess of that possible by other means, but it still offers some advantages, in that small and frequent trains can be run with economy, thus creating traffic by improving the service. In the case of long-distance express service, the advantages of running frequent small trains diminish, since, when most of the energy is expended against wind resistance, the expenditure per coach is considerably greater for small than for large trains. It is only where the traffic is dense that any appreciable advantage in electrification can be shown in this class of service. The above remarks apply to the electrification of existing steam-operated lines in this country. In the case of entirely new railways, the total capital outlay would be less, and a strong case for electrical operation could be made out.

THE MAJORANA SYSTEM OF WIRELESS TELEPHONY

FOR some years past, Professor Quirino Majorana, director of l'Institut Superieur Postale Telegraphique, at Rome, has been working upon the problem of telephoning without wires, and an account of his experiments, by A. Carletti, appears in *Telephony* (Chicago).

In his first experiments, Professor Majorana employed a rotating oscillator which consisted of a motor, upon the axis of which was fixed a disk of ebonite which carried upon its opposite faces two rings of metal. Upon these rings there rested two metal brushes, connected to the discharge circuit. Two steel wires, 2 mm. in diameter, and about 10 cm. long, were attached to the metallic rings, and their extremities formed a spark-gap. The two wires of the oscillator were connected to the secondary of a static transformer, of which the primary winding was traversed by alternating current from the electric light mains. While the motor was running, the two wires of the oscillator turned with it. The sparks which passed across the gap between the two wires were then subjected to violent air pressure, and, consequently, each one was separated and broken up into a considerable number of minor discharges. With this device Professor Majorana succeeded in producing an interrupted series of sparks at the rate of about 20,000 per second.

For the modulation of these discharges in correspondence with spoken words, Professor Majorana built, during the year 1905, a "hydraulic" transmitter, capable of supporting considerable differences of potential, and not liable to heat up too much on being traversed by currents of several amperes. This apparatus is based upon the capillary properties of liquid jets, and consists essentially of a small tube of glass, from the opening in which spurts a jet of slightly acidulated water under a carefully regulated pressure. The small tube is fixed to the diaphragm of the transmitter, of which it can follow the vibrations. The liquid jet falls a certain distance away between two platinum electrodes, and establishes a liquid connection between them.

At this point one finds the characteristic resistance of the transmitter, which, by its variations, determines the transmission of sounds and of words. When one speaks before the transmitter diaphragm, in the same way as with an ordinary transmitter, the diaphragm vibrates. The little tube, in following the diaphragm, causes contractions in the liquid jet, which, in turn, produce variations in the resistance of the liquid interposed between the two electrodes of platinum. There are thus produced fluctuations of resistance between the electrodes, which are in perfect accordance with the sounds which cause them.

This ingenious transmitter has been tried out upon wire lines, and has given very satisfactory results, making it possible to talk over a distance equal to that from the l'Institut Supérieur Postale Télégraphique, at Rome, to London, a distance of about 2,000 miles. Its use in ordinary telephony, however, has

Digitized by Google

not been adopted on a practical scale, because it necessitates an equipment a little cumbrous and not particularly adapted for subscribers' stations.

On connecting the hydraulic transmitter to the circuit of the rotating oscillator, Professor Majorana succeeded in causing a variation in the intensity of the discharges in correspondence with the sounds set up before the transmitter. With this arrangement, he has been able to reproduce the voice at a considerable distance, and to receive speech by the use of an ordinary wireless telegraph receiver. These were the first results obtained by Professor Majorana during the years 1905 and 1906.

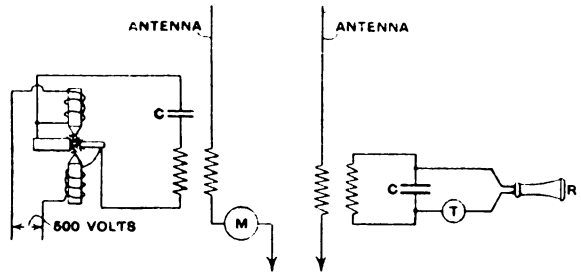

DIAGRAM OF CONNECTIONS OF SENDING AND RECEIVING STATIONS.

In the latest apparatus, however, undamped waves from a Poulsen arc are employed.

The figure represents the arrangement adopted at the transmitting station; the arc enclosed in an atmosphere established between two electrodes, one of carbon, the other of copper. The oscillatory circuit contains a capacity *C*, and the primary winding of a Tesla transformer. One terminal of the secondary of this transformer is connected with the antema, which radiates into space the electric waves which are generated. The other terminal of the secondary is grounded through the hydraulic transmitter *M*.

The arrangement adopted for the receiving station comprises a separate oscillatory circuit, a second antenna, and a thermo-electric detector, *T*, composed of two metals in contact, which under the influence of the waves which strike them, are warmed to a greater or less degree, thus producing modifications of currents in correspondence with the electric waves received, and hence with the voice of the person speaking at the transmitter station. These variations of current are reproduced in the telephone receiver *R*.

With this new system, Professor Majorana has been able to carry on some very interesting experiments between the wireless station at Monte Mario, at Rome, and the station at Anzio, 60 km. distant, as well as with the one at Ponza, 120 km. away. Other experiments have been made between Monte Mario and the torpedo-boat *Lanciere*, while it was 200 km. away on the Mediterranean, and between Monte Mario and the wireless telegraph station at Magdalena, near the island of Sardinia, 300 km. distant.

Other experiments have been made recently between Monte Mario and Trapani, in Sicily, and also between Monte Mario and Messina, in Sicily, about 500 km. away, with results quite satisfactory. Assurance is given that within a short time three wireless telephone stations of the Majorana system will be installed, one at Naples, another at Cagliari, in Sardinia, and a third at Palermo, Sicily.

SOME AFTER-DINNER SPEECHES

Mr. Mordey on British v. German Electrical Engineering,

THERE was a large attendance at the dinner held by the Leeds Local Section of the Institution of Electrical Engineers, on Friday. Mr. H. E. Yerbury, Electrical Engineer to the Sheffield Tramways, who is Chairman of the Section, presided, and Mr. W. M. Mordey, President of the Institution of Electrical Engineers, was present, together with Mr. J. E. Kingsbury, Mr. Robert Hammond, and Mr. J. F. C. Snell, representing the Council, and Mr. P. F. Rowell, the new Secretary of the Institution. Among others present were Mr. Harold Dickinson, Engineer-in-Chief of the Leeds Electricity Supply Department, who is Hon. Secretary of the Section, Mr. A. R. Fearnley (General Manager, Sheffield Corporation Tramways), Mr. J. B. Hamilton (General Manager, Leeds City Tramways), Alderman Ewing Matheson (Chairman of the Electricity Supply Sub-Committee, Leeds), Mr. A. B. Mountain (Chief Electrical Engineer, Huddersfield Corporation), Mr. C. Aspinall Parr (Head of the Electrical Department at the Leeds University), Mr. W. M. Rogerson (Engineer and Manager, Halifax Corporation Tramways), Councillor R. H. Smithson (Chairman of the Joint Tramways and Electricity Committee, Leeds), and Mr. Miles Walker (Chairman of the Manchester Local Section).

Mr. Robert Hammond, in the course of his speech proposing the Corporation of Leeds, mentioned that he had just returned from Turkey, after a three weeks' sojourn there. (The report that Mr. Hammond has been to Turkey to negotiate concessions is incorrect; his visit to Turkey was in view of his suggested appointment as Consulting Engineer to the Turkish Government.) Councillor Smithson responded to the toast, and Alderman Matheson proposed the Institution of Electrical Engineers.

Mr. W. M. Mordey, after acknowledging the toast, referred to the new building on the Thames Embankment, which he said the Institution would occupy by the end of the year; in the meantime the lecture room is being enlarged. He also stated that the Hon. C. A. Parsons had been added to the list of honorary members of the Institution. Incidentally, in speaking of the progress which the electrical industry could make, he said that the new silicon-iron now employed for transformers, as a result of the researches of Sir Robert Hadfield and Prof. Barrett, meant a saving of 30,000 tons of coal during the past few years in the reduction of transformer losses. Mr. Mordey then replied to some of the criticisms made on his recent presidential address. It had been stated that, although the cost of electrical energy might be less, and its sale per inhabitant greater in England than in Germany, the amount of foreign-made plant in the generating stations was still a proof of our backwardness. He had ascertained, however, that, including cables, meters, generating plant, &c., there was probably not more than 5 per cent. of foreign-made machinery and plant, and, he added, probably the proportion of British plant in German stations was greater. Finally, he referred to the "predatory attacks" of promoters upon London electricity supply business, the cost of repelling which, he said, had amounted to 2 per cent. of the capital of the electricity supply companies in the metropolis.

Mr. A. R. Fearnley, who proposed the Leeds Local Section, suggested that it should be called the Yorkshire Section, a proposal from which, we believe, the Institution is not averse, if the majority of the members of the Section desire it. Mr. Yerbury, in responding to the toast, mentioned that there are 265 members of the Section, only 25 per cent. of whom belong to Leeds itself. Councillor W. C. Fenton proposed "Kindred Associations," and Mr. John McLaren replied. The toast of the guests was given by Mr. Dickinson, and acknowledged by Lieut.-Col. Lister (Veritys, Ltd.); and finally Mr. Snell and Mr. T. Harding Churton proposed and seconded a vote of thanks to, and the health of, the Chairman.

Some humorous songs by Mr. S. H. Smith, of the firm of T. Harding Churton & Co., were greeted with much laughter and applause on account of their "topical" allusions both to local politics and to electrical matters.

The fifth annual dinner of the Students' Section of the Institution of Electrical Engineers was held last Thursday evening at the Holborn Restaurant, London, and was a decided success. Mr. E. W. Moss, Vice-Chairman, proposed the toast of the President and the Institution, and Mr. W. M. Mordey and Dr. G. Kapp responded. Mr. Mordey pointed out the fact that of the 6,000 odd members of the Institution, about 1,500 were students. The Students' Section, he said, was not self-supporting, but it was both the duty and the pleasure of the Institution as a whole to afford the student-members the privileges which they had. Mr. Mordey also dealt with the criticisms of his recent presidential address, making a similar statement to that quoted above. Mr. R. Hammond proposed the toast of the Students' Section, which was responded to by the Chairman, Mr. C. B. Nadaud. In the course of his remarks the latter mentioned that a visit of the students to Berlin was being planned for July. Speaking in response to the toast of the Colleges, proposed by Mr. J. Hollingsworth, Prof. S. P. Thompson said that he had found, on comparing the designs of the two houses at home and abroad of a single large company, that the machines of English design were approximately only two-thirds of the weight and cost of machines designed abroad by the same company and for similar guarantees. This was, he thought, due to the greater stress of competition in this country. In conclusion, the toast of the guests was proposed by Mr. B. Thompson, and Mr. J. S. Highfield and Mr. P. Petrie responded. The latter, who is Chairman of the Graduates' Association of the Institution of Mechanical Engineers, referred to the possibility of co-operation on the part of the students of the various Institutions with regard to meetings. An excellent musical programme had been arranged, and was much appreciated by all present.

At the dinner of the Central Technical College Old Students' Association on Saturday, Dr. H. T. Bovey, F.R.S., Principal of the Imperial College of Technology, was the guest of the evening, and proposed the toast of the Old Students' Association. Mr. H. A. Humphrey, one of the first students of the College, and President of the Association for the coming year, was in the chair, and responded to the toast. Dr. T. M. Lowry proposed the visitors, and Prof. J. Perry replied with his customary humour and enthusiasm. Among the distinguished guests were Prof. H. E. Armstrong, Prof. W. J. Pope, F.R.S., Mr. T. Mather, F.R.S., and Mr. J. H. Rider.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 18th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

2,281/08. **Bedside Switch.** B. M. Drake, A. Barnes, and Drake & Gorham, Ltd. This consists of a Bowden wire, one end of which is attached to the lever of a switch near the bed and the other end to a knob sliding in a frame attached to the outer covering of the wire. The danger due to the use of live wires near the bed is thus avoided. Two claims, three figures.

7,854/08. **Ventilation of Machines.** J. P. Hall. A ventilating fan is attached to the rotor of the machine, and a casing is provided with inlet and outlet openings at opposite ends below the shaft. The openings are arranged so as to prevent the entrance of rain or water falling over the machine. Air is drawn through the machine, as the fan is situated at the outlet end. One claim, two figures.

10,893/08. **Continuous-current Meter.** Chamberlain & Hookham, Ltd., and S. H. Holden. This is a watt-hour meter of the type in which a metal disc rotates in mercury between the poles of an electromagnet. The magnetic circuit is formed of iron washers threaded on brass rods and separated by thin layers of paper. This division of the core into a number of short lengths decreases the effect of residual magnetism, and, by the use of a nearly complete magnetic circuit, the meter is rendered less susceptible to external magnetic fields. A special bracket for the support of the counting train, brake magnets, and the upper bearing for the armature spindle, which renders access to the mercury chamber easy, is also described. Three claims, three figures.

14,982/08. **Flame Arc Lamp.** Veritys, Ltd., and F. S. Worsley. Some special features in the mechanical construction of a flame arc lamp with converging carbons are described in this specification. Besides the two rigid rods connecting the economiser frame with the crown of the lamp, other metal rods with adjustable screw connections for strengthening the framework are provided. These latter may be in two or more parts insulated from one another, and can then be used as conductors for connecting up the various parts of the lamp. The central support for the sliding yoke of the carbon-holders is hollow, and contains the rod belonging to the striking mechanism. Four claims, two figures.

15,641/08. **Armouring for Trailing Cables.** British Insulated & Helsby Cables, Ltd., and F. A. Cole. When trailing cables used in connection with portable machinery or for temporary work are protected with an armouring of round steel wire wound spirally, kinking readily occurs, as the wire covering is easily displaced. According to the present invention, it is proposed to cover such cables with steel tape or strip wound spirally, the turns being spaced slightly apart. For example, a one-inch diameter cable would be wound with strip measuring $\frac{1}{4}$ in. wide by $\frac{1}{8}$ in. thick, and a space of $\frac{1}{16}$ in. wide would be left between adjacent turns. A cable armoured in this way cannot be bent beyond a certain limit, as the square faces of the strip bear against one another. Three claims, two figures.

22,105/08. **Speed Indicators.** Hartmann & Braun Akt.-Ges. Various combinations of hot-wire and the Hartmann-Kempf resonance instruments are described. For example, a single instrument may contain a pointer operated by a hot-wire and a row of vibrating reeds. Both the hot-wire circuit and the electromagnet controlling the reeds can be supplied from the same magneto-generator geared to the shaft of the machine. The pointer may indicate the whole range of speed from zero to any maximum required, while the reeds may extend over a short range including the normal speed. By means of an adjustable resistance in series with the hot-wire this portion of the instrument can be readily calibrated by comparison with the reeds, which must be accurate. Six claims, six figures.

22,215/08. **Apparatus for Indicating Faults on High-tension Systems.** C. Linke. Solenoids containing iron cores are placed in the high-tension circuit in the transformer, or other sub-stations, and when an overload occurs the cores are sucked down, thereby releasing indicating apparatus. Two claims, five figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Arc Lamps. Jones, 4,977/08.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: Hobart, Cramer, and Coad [Transformer distribution system] 28,662/07 Brook and Hirst [Resistances] 1,491/08; Rawlings [Conduit fasteners] 4,695/08; Horn [Fixing insulators on poles] 7,490/08; Rorke and Rorke [Heating apparatus] 9,481/08; Taylor [Storage-battery sub-stations] 1,092/09.

Dynamos, Motors, and Transformers: Still [Generators] 2,411/08; Pearson [Speed control of motors] 9,051/08; British Thomson-Houston Co. (*Allgemeine Elektricitäts-Ges.*) [Motor control] 16,621/08; Siemens Bros. Dynamo Works, Ltd. (*Siemens-Schuckertwerke-Ges.*) [Securing end-connections of rotors] 19,720/08.

Electrometallurgy and Electrochemistry: British Thomson-Houston Co. [Furnaces for reduction of ores] 4,644/08.

Ignition, Electric: Maddick [Gas lighting] 4,885/08; Bevis & Coates [Explosion engines] 10,918/08.

Incandescent Lamps: British Thomson-Houston Co. (*General Electric Co., U.S.A.*) [Filaments] 10,590/08.

Instruments and Meters: Orling, Oldenbourg, and Spiegelberg [Electro-capillary device for recording electric impulses] 275/09.

Switchgear, Fuses, and Fittings: North and Orchard [Relays] 2,581/08; Kallmann [Motor-starters] 9,859/08; Lindquist [A.-C. electromagnet] 11,806/08; Boult [*Benjamin Electric Manufacturing Co.*] [Terminals and contact-pieces] 14,411/08; Hallock [Motor controllers] 23,602/08.

Telephony and Telegraphy: Lemoine [Automatic transmission] 24,197/07; Stolz and Viggars [Telephonic Apparatus] 13,875/08.

Traction: Briggs [Tramway rails] 14,510/08; Melling [Brakes] 15,973/08; Beach [Current-collectors and control systems] 19,054/08.

Miscellaneous: Archer [Hauling gear] 2,163/08; Whittington [Electrically fired rifles] 2,629/08; Houghton [High-frequency medical apparatus] 9,042/08; Lyon [Air heater] 18,735/08; Trautmann [Burglar alarm] 24,013/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

Akt.-Ges. Brown, Boveri, et Cie [Regulation of machines] 19,921/08; Johannet [Electromagnetic speed-gear] 28,438/08; Taylor [Signalling systems] 1,788/09; Brüll [Resistances] 1,998/09; Centralstelle für Wissenschaftlich-technische Untersuchungen-Ges. [Production of long arcs] 2,216/09; Heyland [A.-C. regulating system] 2,520/09; Ryan [Gun control] 2,634/08; Akt.-Ges. Stahlwerke Weissenfels vorm. Goppinger & Co. [Chain welding] 2,642/09.

Expiring and Expired Patents

The following patent expires during the current week after a life of fourteen years:—

4,577 of March 4th, 1895. **Electric Ignition of Miners' Safety Lamps.** W. Ackroyd and W. Best. An apparatus consisting of a battery and an induction coil fitted in a case with a special compartment for receiving the lamp, is described in this specification. A lamp in which the wick is ignited by a discharge between the wick tube and a special insulated conductor, and which is provided with a contact for connecting up the lamp when in the ignition chamber, is also described.

The following are the more important patents that have become void through non-payment of renewal fees:

Arc Lamps: H. C. Levis (*A. G. Davis*) [Regulation of mercury vapour lamps] 24,142/03.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: T. J. McTighe [Cable terminals and rail bonds] 19,509/00; L. H. Lander and Simplex Steel Conduit Co., Ltd. [Inspection fitting for conduit wiring] 22,012/01.

Dynamos, Motors, and Transformers: British Thomson-Houston Co., Ltd. (*C. P. Steinmetz*) [Squirrel-cage induction motors] 19,496/00; O. H. Pieper and A. F. Pieper [A.-C. commutator motor] 22,110/01; O. H. Pieper [A.-C. commutator motors] 23,971/02; J. W. Macfarlane [Lubrication of vertical shaft motors] 24,033/02; Siemens Bros. & Co., Ltd. (*Siemens & Halske Akt.-Ges.*) [Motor control] 23,664/03; A. P. Zani [Alternator construction] 24,129/03.

Electrometallurgy and Electrochemistry: H. Nehmer [Dry battery] 23,712/03.

Ignition, Electric: O. von Morstein [Gas jets] 20,801/95.

Incandescent Lamps: British Thomson-Houston Co., Ltd. (*C. P. Steinmetz*) [Non-metallic compound filaments] 22,088/99.

Instruments and Meters: J. T. Armstrong and A. Orling [Electro-capillary relays] 21,981/01; R. P. Wilson and G. M. Hardingham [Photometric apparatus] 24,325/02; O. Imray (*Siemens Schuckertwerke-Ges.*) [A.-C. meter] 23,854/03.

Switchgear, Fuses and Fittings: British Thomson-Houston Co., Ltd. (*E. M. Hewlett*) [Multiple-point switch for heavy currents] 19,500/00.

Telephony and Telegraphy: J. Burry [Printing telegraphs] 19,824/00.

Traction: H. H. Lake (*J. Dulait, L. Rosenfeld, and C. Zelenay*) [Polyphase system with stator laid in track] 22,298/01.

Miscellaneous: J. W. Hall [Electromagnetic speed-gear] 22,406/01; H. von Köhler [Log recording apparatus] 23,862/03.

GAS ENGINES v. STEAM TURBINES

MESSRS. ANDREWS and Porter's Paper on "The Use of Large Gas Engines for Generating Electric Power," published in an abridged form in our last issue, was discussed in Dublin on February 11th and in Manchester on February 17th.

DISCUSSION IN DUBLIN.

MR. J. STURGEON (Joint Consulting Engineer to the Central Ireland Electrical Power Scheme) was practically in agreement with everything stated in the Paper, with the exception that he thought that the advantages of the large gas engine units advocated by the authors were perhaps open to criticism. He had obtained estimates for two 500-kw. sets with rope driving and fitted with 15-ton flywheels; the price, including three-phase generators, was £13,040, while a single set for 1,000 kw., with engine running at 88 r.p.m., and a 24-ton flywheel, cost £13,300, and the thermal efficiency was the same. He had also found that British makers fought shy of large-sized engines. Other points in favour of the smaller sets were, that the foundations for the larger engines were dearer in proportion, that the crane would require to deal with weights 60 per cent. heavier, and would have to be given a wider span. Taking all these facts into consideration, he thought that the 500-kw. size was the handier and one which makers had had experience of. In connection with the Central Ireland Power Co., which intended to use peat for gas production, the value of the sulphate of ammonia recovered was such that it would actually pay to keep the gas-producers in operation, whether power was required or not, thus showing how very cheap electrical energy could be sold to consumers who required it for such processes as electrochemical or electrolytic possessing a load factor bordering upon 100 per cent. The speaker noticed that the authors anticipated a yield of 90 lbs. of ammonium sulphate per ton of coal consumed, while using peat he expected to obtain 1 cwt. per ton of dry peat.

Mr. G. M. HARRISS said that his experience with large gas engines was chiefly with the 500-kw. National set, which ran side by side with steam sets at the Irish International Exhibition. He remembered that the Exhibition authorities tried nearly every maker to get such an engine, but most of them would not touch anything like the size required. The engine was made and put down in a hurry. The first night it started it was put on full load, and no hitch whatever occurred. It was often over-loaded, but ran right through the Exhibition equally as well as the four steam sets. He had no hesitation in saying that, in his opinion, it would not be very long before gas engines would entirely take the place of steam engines.

Mr. W. J. SOWTER (Chief Electrical Engineer, Bray Urban District Council) was rather disappointed with the authors' deductions, as he had imagined that a very much better case could be made out for gas engines. True, a saving of 45 per cent. was shown (with the aid of the ammonia-recovery plant), but the question was, whether responsible engineers would consider such a prospective saving sufficient to warrant their entering upon what was, so far as this country at any rate is concerned, a huge experiment. He objected to the steam station being penalised to the extent of over £2,000 per annum for water supply, as no engineer would think of putting down a turbine station inland if a good supply of water could be got, even if there were serious disadvantages in other directions. He also wished to know why steam-driven exciters were to be put down in the gas-driven station instead of the exciters being direct-coupled to their own alternators. He was surprised to hear that the capital cost of gas-engine plants per kw. was so much higher than steam. He had recently got prices for 100- to 200-kw. direct-coupled high-speed gas engines and dynamos, and had come to the conclusion that the cost was almost exactly the same as an up-to-date steam station. Mr. Sowter thought that the authors could have made out a very much better case for the use of gas engines for small stations having capacities of only a few hundred kw., as the coal consumption per unit with steam sets was high, while the small gas engines were practically as economical as the larger sizes.

Mr. W. TATLOW mentioned a case in America where a kw. plant had been put down to act as a stand-by in case the transmission line failed. He thought it a great pity that the lamentable failure of the Johannesburg plant had been so much talked about, as no doubt that had acted as a deterrent to the adoption of large gas plants. Probably the conditions there were very severe, but he saw no reason why these large plants should not be a success. The price of coal was not likely to fall, and as in large power plants the cost of fuel was frequently 80 per cent. of the total cost of generation, engineers would do well to consider seriously the advantages of gas plant. He (Mr. Tatlow) thought that the authors had been rather unfair in their remarks regarding the comparative reliability of gas engines and steam turbines. Finally, he was rather surprised that no gas-engine maker had attempted to apply the Diesel cycle to a gas engine using gas; the impulses were very much less violent and the expansion gradual in a Diesel engine, thus more nearly approximating to the action of a steam engine.

Mr. T. TOMLINSON was particularly pleased to note the method by which the authors had arrived at the probable coal costs in the cases they had given, as in a recent communication to the Engineering and Scientific Association of Ireland he had enunciated the same method. The value of the Paper rested in the fact that the figures given did not merely represent results achieved at two different stations, where perhaps the conditions might be widely different, but were figures arrived at by an accurate process of deduction, and even if the totals were not strictly accurate, the comparisons between the two cases were probably so. Mr. Tomlinson did not quite see how the authors managed to get any overload capacity at all out of a gas engine, but, of course, it was all a matter of rating.

Mr. P. H. STEWART (Electrical Engineer, Messrs. A. Guinness, Sons & Co.) suggested that if large stations were started all over the country producing sulphate in such enormous quantities, the market price would fall and the price of sulphuric acid increase. Referring to steam turbines, Mr. Stewart said that he had had no trouble whatever with them, and had never known the blades to strip.

Mr. J. STURGEON, referring to the last speaker's remarks regarding sulphate of ammonia, said that before Dr. Mond started his gas plants the price was £7 per ton. The output was then increased as the value of the material became better known, and instead of the price falling it increased to nearly £12 per ton; the lowest price last year was £11 15s., and the average for the year was £12 15s. 8d. The world's demand was now enormous, and he did not think there was any fear of a "slump."

Mr. A. T. KINSEY (Assistant Superintending Engineer, Dublin G.P.O.) was pleased to see that the authors did not compare new gas engines with old steam engines, but new gas engines with the modern turbine. He knew of two towns in Ireland having public electricity supplies. One had water power and charged 5d. per unit; the other had suction-gas plant and charged only 3d. He had seen both plants, and was astonished to find electricity could be obtained in a small town in Ireland at 3d. per unit: there was no sulphate plant in connection therewith, but, at the same time, this plant could hold its own with the water-driven plant.

Mr. S. F. PILDITCH (Chief Electrical Engineer, Rathmines and Rathgar U.D.C.), the Chairman, in closing the discussion, thought that in the future gas engines would run steam very close, although it appeared from the Paper that the capital costs were considerably higher. He should have rather expected that the cost of repairs and maintenance of gas engines, &c., would have been considerably greater than steam, but apparently such was not the case.

DISCUSSION IN MANCHESTER.

Mr. C. E. DOUGLAS (Mather & Platt, Ltd.) said that stations such as the authors had shown illustrations of, with 60,000 h.p. of gas engines in one installation, gave considerable hope indeed for the large gas internal-combustion engine, but he did not think that the field would be opened to them just yet as against the large steam turbine. On the other hand, where units do not exceed 1,000 kw., his opinion was that the capital cost of the steam installation would be practically on a par with the gas installation. He thought that the authors' figures for coal consumption were a very fair average indeed for both steam and gas stations, but from his own experience he would have thought that a discrepancy factor of 25 per cent. was not enough, and the Lancashire mill-owner and the Yorkshire woollen manufacturer would not allow less than 10 per cent. for interest and depreciation. In the south of England he believed that there was a big field for gas-engine work, for there would be a saving in the coal costs through burning a cheaper grade of fuel. Lastly, he was able to confirm the authors' statement as to parallel running; single-acting gas engines had, he said, been running alternators in parallel for the last six or seven years, and now it was of common occurrence.

Mr. S. L. PEARCE (Chief Electrical Engineer, Manchester Corporation) was inclined to think that Mr. Andrews' view, as expressed in ELECTRICAL ENGINEERING in October, 1907, in which he advocated a combination of gas plants with steam plants, was sounder than the one he had now taken up, in which he "plumped" for gas plants. The disadvantages of gas plants were admittedly (1) the excessive weight, (2) the inability to meet sudden overloads, and (3) the extra space taken up, and each engineer must consider these points in relation to his own local conditions. Through the courtesy of Mr. Andrews and other friends, Mr. Pearce continued, he had been able to see a good deal of large gas-engine plant at work on the Continent, and he was prepared to say that the large gas-engine unit to-day is a thoroughly reliable article. On the Continent, however, it is a question of blast-furnace gas or coke-oven gas, and more information was desirable as to whether the producer end is as satisfactory as the gas engine itself.

Dealing with the question of the size of unit at Manchester, they could not possibly consider putting in units of anything below, say, 5,000 K.V.A. capacity. With regard to the capital costs given in the Paper, he would say generally that the steam figures appeared about 10 per cent. too high, and that the capital

Digitized by Google

costs for a gas plant using 5,000 K.V.A. units could probably be brought down to £15 per kw. Then the figure of 1 lb. of fuel per kw.-hour for a gas plant did not appear to be borne out in practice, especially if, as he supposed, the figure referred to the actual units sent out on the feeders. The table of actual results appended to the Paper did not bear out this figure, and, furthermore, some figures were put before him some time ago by a firm of gas-engine builders, and although they were considering a set of conditions in which the size of unit was some 4,000 kw. and the load factor would be at least 70 per cent., the guaranteed figure worked out to about 1¾ lbs. There was not, in his opinion, more than 1 lb. per unit to be saved as between a gas and a steam station. The authors' estimate of £11 per ton as the value of the sulphate of ammonia by-product was very near the mark; the gas department of the Manchester Corporation for the last three contracts had obtained, he thought, £10 15s., but if the supply of these by-products was likely to become extensive, they might fall, and it was not right to figure on maintaining the price of £11 per ton. Some seven or eight years ago, when first he came to Manchester, the speaker had made some tests with a view to arriving at the stand-by coal figure on the city station's plant, and he had arrived at 5 lbs. of coal per day per kw. installed, which was almost identical with the authors' figures. In the curves given in the Paper, one was included for a 6,000-kw. turbo-alternator at Stuart Street station, Manchester, and the authors had assumed that the no-load losses were 15,000 lbs. of steam per hour. This, Mr. Pearce said, was not correct; the figure should really be 9,600. Continuing, Mr. Pearce characterised as excessive the authors' 288,000 gallons of cooling water per hour (70 times the weight of steam). Their allowance for repairs of the steam plant was also on the high side. He wished to know, also, why the authors think that the repairs for generators would certainly be lower for gas-driven plant than for steam or turbine driven. Experience at Manchester went to show that the turbo-alternators were more likely to cost far less in upkeep than reciprocating slow-speed sets. For depreciation and interest, Mr. Pearce suggested an equated figure of 8½ per cent. for gas and steam, based on the lines of the separate parts of the installations. Subject to these foregoing criticisms, Mr. Pearce amended the estimates for gas and steam to 0·423d. as the total costs per unit for the former, and 0·483d. for the latter, still showing a substantial advantage to the former. The effect of fuel price and load factor was, Mr. Pearce explained, the whole gist of the question. Under the second set of conditions given, he thought that the authors had set out to prove too much. He had taken out a series of figures in detail, and, taking coal at 10s. per ton and a 10 per cent. load factor, had arrived at a total cost per unit generated for gas of 0·835d. per unit as against 0·8d. for steam.

Mr. W. STEAD (British Westinghouse Electric and Manufacturing Co., Ltd.), who is in the fortunate position of having to deal with gas engines and steam turbines, both in manufacture and in operation, said that at the Westinghouse works they had about 1,200 b.h.p. of gas engines, and the remainder were reciprocating Corliss steam engines. If they have to shut down the gas engines on account of using the gas for other purposes in the works, they very soon feel it in the coal bill. Their two producers, he said, had been at work now for about four years. They are Mond producers of 1,000 h.p. each. In that time they have re-lined their producers, at a cost of about £75 each, and that was practically the only repair. The other portion of the producer, the outside work, he said, does not deteriorate, such as boiler work. The only trouble in a producer job is that particular care has to be taken with the tar, and the producer people as a whole certainly underestimate the evil effects of tar. Recently, Mr. Stead added, a Liverpool firm had produced a burner for tar, which could be used in connection with a boiler; 23 cwt. of tar would take the place of a ton of coal. On the question of economy of gas engines, he said that in a mill where a Westinghouse gas engine is installed they run at 1·2 lbs. of coal per b.h.p. The h.p. is about 750, and the coal is 1s. 6d. per ton cheaper than that which would be supplied to a corresponding Lancashire boiler used for driving the weaving shed. He thought that all makers of steam or gas engine plants would very much like to have the figures quoted by the authors at the present time.

Dr. F. H. BOWMAN held that the gas engine is not so perfect as the producer is to-day, and especially the continuous action suction producer. He estimated the cost of a 500-h.p. suction producer plant at less than £1 per h.p., and said that there was absolutely nothing whatever to get wrong if it was put down properly. Anthracite was the best fuel for such a case, but dear, and he suggested using a mixture of anthracite and gas coke. The cost in fuel would, he said, be about ⅛d. per b.h.p.-hour. His opinion with regard to bituminous plant was that it would not pay to put down a recovery plant for less than, say, 4,000 h.p.

Mr. S. J. WATSON (Chief Electrical Engineer, Bury Corporation) said that after a visit which he had made with Mr. Andrews and a party of engineers last summer, he had come back absolutely convinced that the large gas engine was a practical piece of mechanism. One of the places visited contained some 12 sets of engines, each of over 2,000 h.p., in an engine-room 230 ft. long by 260 ft. wide. Mr. Watson thought it rather unfortunate that the authors should have put forward figures for a large turbine station with cooling towers, for this was the exception, and they made a considerable difference in the capital expenditure. In addition, the estimates of capital expenditure omitted any reference to the cost of the land, and the gas-engine station would cost double for land as compared with the turbine station. He thought that a station of the size given could be put down at £117,500, assuming ample water supply. This worked out to about £11 15s. per kw. (excluding the buildings), compared with the authors' figure of £13 9s. Adding the buildings, the cost came to about £18 per kw. On the question of running costs, Mr. Watson thought that 3·55 lbs. per unit generated was bettered in several cases, and he felt certain that a cheaper quality of fuel could be used for the boilers than for the producers. Making these adjustments, and allowing for the reduced capital charges, Mr. Watson found that with 24 per cent. load factor, the costs came out practically identical, and consequently with half the load factor the savings effected owing to the reduced capital charges on the steam plant showed up the steam plant to a very much better advantage. He agreed with Mr. Pearce that a combination of steam and gas plant might give better results. He also asked whether Mr. Andrews allows anything extra for insurance or compensation, owing to the possibility of men being "gassed."

Mr. V. A. H. M'COWEN (Chief Electrical Engineer, Salford Corporation) said that, taking an average over the preceding five years, the price of coal at Salford came out at something like 8s. per ton. This would reduce the cost of fuel in the case of steam from £19,000 to about £15,000, and in the case of gas from £12,000 to £8,000, which would benefit the steam scheme by about £3,500 a year from the fuel point alone. Sixpence per 1,000 gallons of cooling water was also an excessive figure, and in his district he thought it was quite possible to get it at possibly a sixth of that price by bore-holes. That would reduce the cost of water in the case of the steam scheme from £2,500 to about £350, and reduce the cost of water in the gas scheme to only about £90. The capital costs could also be reduced by the price of the cooling towers, and he saw no reason why the size of the boiler units, viz., 10,000 lbs. capacity each, should not be doubled. This would reduce the capital outlay on the boilers, the radiation losses, and also the space necessary. He also considered the discrepancy factor much too high, and the 25 per cent. increase on the coal in both cases meant an increase of 6,600 tons on the steam scheme, as against an increase of 3,000 tons in the case of the gas scheme. He also maintained that the ground space occupied in the steam scheme might be reduced at least 25 per cent. by rearrangement of the plant, and that it would be very little more than a third of the area for the gas scheme.

Mr. G. D. SEATON (Willans & Robinson, Ltd.) said that if he had his way he would alter the title of the Paper to "German Gas Engines *v.* English Turbines." He had been a good deal in Germany himself, but never as a guest of Mr. Andrews on one of those pleasant little jaunts that he had engineered, but in order to chase Free Fooders, and to prevent them from running amuck and leaving their orders in Germany. The big German gas engines were, he said, undoubtedly a success; they were all working with blast-furnace gas, the ideal gas for gas engines. On the other hand, the bituminous producer was not a success, and if the authors had had any reliable figures about the working of big bituminous producer plants, he thought that they would have preferred to substitute them for the hypothetical figures they had had to rely upon. If there was the slightest trouble with plant, the station engineers were on the telephone to the contractor's man immediately, and if they were going to have serious difficulties they would exercise the rejection clause, and generally make the life of the contractor's man a burden. When Messrs. Andrews and Porter had succeeded in getting a producer station at work, he was afraid they were going to have to put up with a great deal more than he himself had to put up with, and he was rather inclined to think that the finish of that big producer station would be another case of "Oh, Mr. Porter, what shall I do?"

Mr. J. ATKINSON (Crossley Bros., Ltd.) wished to emphasise the fact stated in one of the tables in the Paper, that the average overall efficiency of the gas plant was more than twice as great as the overall efficiency of the steam plant. On one point he differed from the authors, for it appeared to him that the lower the load factor, the greater the need for gas engines. The authors were correct in speaking of the difficulty of using gases containing a large percentage of hydrogen, but his own experience, when working engines with different kinds of gas, had been that dust had caused more trouble and difficulty than hydrogen. For some considerable time a plant of about 3,000 kw., working with bituminous coal, had been working at Crossley Bros.' works, in which the ammonia absorber and the washer had been combined in the one part, thus eliminating the ammonia absorber. This arrangement had been found to extract ammonia with quite as great an efficiency as by having a separate absorber. Finally, he thought that the gas plant should be worked with a fewer number of men than the steam plant.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield Corporation), who sent his remarks in writing, said that rather than have the cooling tower conditions assumed by the authors he would not put down turbines at all, but reciprocating engines. For a maximum of 8,000 kw., he would not install five 2,000-kw.

Digitized by Google

machines, but two 4,000-6,000 units and two of 2,000-3,000 kw. The cost of these four machines, including condensers, pumps, circulating pipes, &c., should not be more than £42,000, against the authors' price of £50,575, and the steam and coal consumptions, would be very much better than those given in the Paper. His present coal consumption with a much smaller load, both as regards maximum demand and load factor, was now considerably below 3 lbs. per unit generated, compared with the authors' figure of 3·55 lbs. per unit generated. Instead of putting down 20 boilers of 10,000 lbs. capacity, he should prefer six boilers with a normal capacity of 30,000 lbs., each capable on emergency of steaming at least 50,000 lbs., similar to those he had had in use for the past four or five years, at a total cost, including economisers, chimneys, fans, foundations, and everything, of £21,000, which is £10,000 cheaper than the authors' figure; and, further, his figure includes the foundations, chimneys, and flues, which the authors have included in the building item of £33,600. On these two items alone, therefore, the authors' capital expenditure estimate for steam plant would be reduced by £20,000, and he believed that by going carefully into all the other items, the total amount of £139,525 could be brought to something near £100,000 for the steam plant, as the cooling towers should be struck out altogether.

The Authors have sent us their reply to the Manchester discussion, in which they say that, if central station engineers omit to avail themselves of the high thermal efficiency of the gas engine, industrial users will then find it cheaper to generate their own current in isolated small plants. They agree with Mr. Pearce that combined gas and steam stations will be largely used in future, because steam plants are already installed in the majority of supply stations, and will undoubtedly be retained for the peak load, gas engines being used for the flat portion of the curve. They maintain, however, that in laying out a new station there is no advantage in installing combined plant. They suggest that Mr. Pearce has overlooked the fact that the 1 lb. of fuel per kw. generated by gas engines is the fuel for extra current only, and say that their estimate of the total consumption at 2·18 lbs. is considerably higher than any of the actual gas-engine consumptions recorded in a list of actual results. They are pleased to have Mr. Stead's testimony of the reliability and low cost of repairs to producers as a confirmation of similar reports they have received from other users, and they contend that the apparent feeling of uneasiness respecting the producer end of the problem arises entirely from lack of experience. They also confirm Mr. Stead's opinion that it is not necessary to use a more expensive coal for generating gas in producers than for steam raising. In reply to Mr. Seaton, they point out that numbers of large gas engines are running on coke oven gas, which is a much more difficult problem than working on producer gas.

LOCAL NOTES

BELFAST: *Harbour Electricity Supply.*—At the fortnightly meeting of the Harbour Commissioners last week it was stated that no reply had been received from the Corporation with regard to the supply of electrical energy, and the question of whether an independent plant should be put down was again referred back to the Works Committee.

Cavehill and Whitewell Tramways.—At the weekly meeting of the Electrical and Tramway Committee on the 22nd inst., a motion to have counsel's opinion on the proposed agreement between the Cavehill and Whitewell Tramway Co. and the Corporation re-submitted to the company was discussed, and also an amendment to drop the scheme. The motion was carried by the casting vote of the Lord Mayor, five being for and five against.

BIRMINGHAM: *Electric Supply Charges.*—The Electric Supply Committee propose a revised scale of charges for electricity for lighting purposes and for low-tension power supply. For ordinary lighting the charge commences at 4d. per unit for any quantity up to 1,000 units per quarter, and is reduced to 2d. per unit for 20,000 units per quarter and over. Discounts are also allowed for quantities over 50,000 units. Long hour lighting consumers commence at 2¼d. per unit up to 2,000 units per quarter, with 2d. per unit above this quantity, and discounts. The charge for power supply commences at 1·55d. per unit up to 1,000 units per quarter, and gradually comes down to 1·1d. per unit for 60,000 units per quarter and upwards. A special restricted hour rate has been fixed, under which the consumer has to enter into a five years' agreement and take 80 per cent. of the supply between 6 p.m. and midnight. A tariff has also been devised for block arc lighting. For a minimum of four 8-ampere arc lamps installed on any one service a charge of £5 per lamp per annum is made, to include the cost of current, trimming, cleaning, and recarboning the lamps, and switching on and off. This charge provides for the lamp being used for 420 hours per annum. If the lamps are required beyond this time, 2d. per hour per lamp is charged in addition. For stand-by supply a minimum charge of £4 per annum per kilowatt of possible maximum demand is to be made. Current can be used up to this value at ordinary rates without further charge. Any current taken in excess of this amount is charged at the ordinary rates.

BRIGHTON: *The Electricity Works.*—Councillor Hallett at the last meeting of the Corporation persisted in his amendment that the consideration of the report with regard to new plant referred to in our last issue should be postponed for a fortnight, and that, meanwhile, the consulting engineer should report (1) whether an equal efficiency to that of Southwick had been obtained elsewhere at less cost, and (2) whether the proposed expenditure on new boiler plant can be delayed for one year without risk. The amendment was carried by the casting vote of the Chairman.

The Corporation have since approved the recommendation of the Electric Light Committee to spend £15,370 on the provision of additional boiler plant at the Southwick Electricity Works.

BRECHIN: *Assessment of Electricity Works.*—The North of Scotland Electric Light & Power Co. recently appealed against the assessment of their undertaking, which was put at £660. It was argued that the proper method of assessment was upon the revenue basis and not upon the capital expenditure, in which case the assessment would be £200. The Appeal Court decided in the company's favour. It may be pointed out that the magistrate had previously decided that the assessment should be £400.

DUNDEE: *Electrical Contractors' Dinner.*—The annual dinner of the Dundee branch of the Electrical Contractors' Association was held last week. Mr. H. Richardson, the City Electrical Engineer, urged the contractors to push ahead, and they would not lack support in developing their business.

FARNHAM: *Overhead Wires.*—The Board of Trade have informed the Council that the application of the Farnham and District Electric Lighting Co., for permission to erect overhead wires, has been refused. The reason given is that the Board disapproves of the erection of overhead wires for electric lighting in populous places. We reported the local inquiry in our issue for December 31st, 1908, p. 849.

GLASGOW: *Power Rates.*—A new scale of charges for large power consumers is to be put into force. This applies to consumers of not less than 500,000 units per annum.

GRIMSBY: *Wireless Telegraphy.*—The Admiralty has made a payment to the Corporation of £1,400 on account of the Admiralty wireless telegraph station at Humberstone.

HANLEY: *Plant Insurance.*—The fire insurance policy on the plant in the power-house has been increased to £17,800 in order to include the new machinery now being installed.

HUDDERSFIELD: *Electricity Works Profits.*—During 1908 the income of the Corporation electricity department was £31,614, against £30,353 in the previous year. The expenditure was £19,600, against £19,369 in 1907, leaving a surplus balance of £12,013, against £10,983 in the preceding year. After providing for interest on loans, sinking fund reduction, &c., a net surplus of £550 remained, against £985 at the end of 1907. The depreciation and contingencies fund, after adding the net profit, has been reduced by payments from £11,874 to £4,066.

HULL: *Tramway Accounts.*—The Tramway Committee estimate that for the financial year ending March 31st next the income from the tramways will be £128,691, and the expenditure £106,282, leaving a surplus, after the interest and sinking fund had been paid, of £22,409, as against £29,895 last year, being a decrease of £7,486. The wages account shows a remarkable increase of some thousands of pounds. A recommendation is to be made to the Corporation that the sum of £18,000 be contributed to the relief of rates.

HYTHE: *The Tramway Question.*—Having considered the letter from the National Electric Construction Co., referred to in our last issue, the Council have decided to petition against the Bill which has been deposited by the company asking for authority to use the overhead trolley system. In recommending this course of action, the Town Clerk pointed out that it did not prevent the parties coming to an agreement.

KIRKBY-IN-ASHFIELD.—The Board of Trade have revoked the Electric Lighting Order granted to the Council in 1904.

LANCASTER: *Tramways Arbitration.*—The Corporation is to acquire the undertaking of the Lancaster Tramways Co. for £13,391, as the result of arbitration. Pending powers on the part of the Corporation to work the undertaking, the company will continue to operate the cars. An application is to be made to the Local Government Board for a loan to defray the cost of acquiring the undertaking and converting the lines to electric traction.

LEICESTER: *Tramways Report.*—The revenue from the tramways undertaking for 1908 amounted to £117,793, an increase of £947 over that of 1907, but the number of passengers carried showed a decrease of 5,941, viz., 27,411,286. The average receipts per mile were 8·479d. against 8·406d. in 1907. The working expenses amounted to £71,652, an increase of £765 over last year. This was due chiefly to increases in maintenance of permanent way and rolling stock, and power expenses, &c. The gross profit amounted to £46,140, against £45,957, and

Digitized by Google

after deducting interest, sinking fund, and income-tax, there is a net balance of £11,350, against £10,538.

LONDON: *Harrow Road and Paddington Tramways.*—In reference to the proposal of the London County Council, reported in our issue for February 11th, to purchase a portion of this undertaking from the Metropolitan Electric Tramways, Ltd., the Highways Committee now recommend that the Council shall give its consent to the construction of an extension by the company to Edgware Road, and then to grant the company running powers over the complete line upon certain terms which have been embodied in an agreement.

Putney: Tramways.—A meeting of the ratepayers was held last week to protest against the proposal of the London County Council to construct tramways along High Street, Upper Richmond Road, and Oxford Road, and calling upon the Council to substitute the suggested alternative route along the Putney Bridge Road.

Poplar: Encouraging Small Consumers.—In order to encourage the extension of the supply of electricity for domestic purposes, the Council has agreed to a suggestion by the Engineer that an experiment should be made of putting in twenty-five installations free, but without fittings. The proposed charges on these installations will be as follows:—For lighting, £4 per annum per kilowatt installed, and for heating £1 per kilowatt, with an additional charge in each case of ½d. per unit for all current used, and a charge of 12½ per cent. on the Council's cost of installation, to cover depreciation, repairs, and interest. The charge per kilowatt for lighting in cellars, lavatories, &c., would be at the lower rate of £1 where a combined supply for heating and lighting is taken. The estimated cost of the experiment is £375, and if the experiment succeeds a further extension of the service will be considered.

St. Pancras: Tramways.—The Borough Council persist in their refusal to bear any portion of the cost of widening Highgate Hill in connection with the conversion of the cable tramway to electric traction. The Islington Borough Council came to a similar decision a short while ago.

MIRFIELD: *Tramways.*—The District Tradesmen's Association have appointed a deputation to wait upon the British Electric Traction Co. to urge the advisability of extending the tramways from Ravensthorpe to Mirfield. A similar inquiry is to be made of the Huddersfield Corporation.

MAIDSTONE: *Electricity Loans.*—The Local Government Board have informed the Council that they are prepared to sanction a loan of £20,000 to defray expenditure previously incurred in connection with the electricity undertaking, but that the proportions of principal that would have been payable by the Electric Lighting Committee if the loans had been obtained at the proper time, must now be paid out of revenue. Such proportions of principal, with another item directed to be met out of revenue, amount to £1,200, and, the Board continues, it would appear that if they had been included in the balance-sheets of the last two years, together with the proper sums for interest, no profit would have been shown on the undertaking.

MIDDLESBROUGH: *The Trackless Trolley System.*—Mr. H. M. Taylor, the Borough Electrical Engineer, has prepared a report upon the trackless trolley system, in which he suggests its adoption on a circular route of 2½ miles, the estimated cost of which he puts at £12,000. The running costs are put at 7d. per car-mile.

OXFORD: *The Tramway Question.*—Sir Alexander Kennedy, F.R.S., has reported to the Corporation against the use of any surface-contact system for Oxford, and recommends the Council either to oppose the Bill of the National Electric Construction Co.—which seeks to override the agreement with the Council—or else to compromise with the company, on terms, for the installation of a combined trolley and conduit system.

RHONDDA: *Tramwaymen's Strike.*—The employees of the Rhondda Tramways Co. came out on strike on Saturday in order to secure better conditions of service. A local paper states that the trouble was settled in half an hour by the company agreeing to concede the men's demands.

RHYL: *The Proposed Tramway.*—The Light Railway Commissioners held an inquiry last week into the proposed scheme of tramways between Rhyl and Prestatyn. The Council opposed, and it was decided to call a ratepayers' meeting before the Commissioners give a decision. The Prestatyn Council support the scheme subject to satisfactory road widenings.

RUGBY: *Street Lighting.*—A proposal that the street lighting should be converted from gas to electricity has been referred back.

SADDLEWORTH: *Electric Lighting Order Revoked.*—The Board of Trade have revoked the Electric Lighting Order granted to the Council in 1902.

SHEFFIELD: *New Plant.*—A new 4,000-kw. turbo-generator at the Neepsend power station was started up last week.

TORQUAY: *Tramway Extension.*—The Council has given its permission for the tramway company to extend their lines from the existing terminus in Torbay Road to the Borough boundary in Paignton Road on the overhead trolley system, instead of upon the surface-contact system, which is used elsewhere in the town.

TYNEMOUTH: *Report on Electricity Works.*—Messrs. Handcock & Dykes are preparing a report upon the electricity undertaking, and the Borough Treasurer and Electrical Engineer are to visit London in connection with this report.

WEST HAM: *Power Supply.*—A contract has been entered into with the Anglo-Continental Guiano Co. for a supply of current to their works at Silvertown for a period of ten years. The price at which the energy is to be supplied has not been disclosed.

WEYMOUTH: *Trackless Trolley System.*—The Electric Lighting Committee have reported that after considering the trackless trolley system, they have come to the conclusion that it will not be suitable for the requirements of the borough.

YORK: *Tramways.*—The Council has decided to proceed with the construction of their light railway scheme.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

AUSTRIA-HUNGARY.—The *Board of Trade Journal*, quoting from a Continental exchange, states that the proprietors of the Auer Electric Works in Tramin (Tyrol) are about to erect new electrical works in order to keep pace with the increasing demands.

It is also announced that a large electric generating station is about to be erected in Dubitzko (Mähren); and that the local authorities at Sexten (Tyrol) contemplate erecting electrical works there.

BIRMINGHAM.—The Electricity Committee have reported that although in 1907 the Council sanctioned a loan of £80,000 for additional mains, which it was estimated would suffice for three years, owing to the rapid increase in demand further outlay is necessary, and the Committee recommend application for a loan of £100,000, which it is estimated will be sufficient for the next three years. In addition, it is recommended that the following loans should be applied for:—£15,000 in respect of high-tension switch-gear, £2,000 in respect of transformers, and £20,690 in connection with the fitting-up of the Dale End sub-station, and £10,650 for cooling towers at Summer Lane station.

ILKLEY.—A Local Government Board inquiry was held last week into an application by the Council for sanction to borrow £5,700 for various purposes, including the electric lighting of the Town Hall and free library.

RADCLIFFE.—The Council require (1) 300-kw. steam dynamo; (2) 100-kw. motor-generator; (3) automatic three-wire reversible booster; (4) condensing plant, steam and other piping, valves, &c.; (5) switchboard extensions. Particulars from Messrs. Lacey, Sillar & Leigh, 2 Queen Anne's-gate, Westminster, S.W., and tenders by March 2nd.

The Council also invite tenders for a Lancashire boiler and superheater; also for feeder cable. Particulars from the Electrical Engineer, and tenders by March 2nd.

WEST HARTLEPOOL.—A Local Government Board inquiry was held last week at West Hartlepool into an application by the Corporation for sanction to borrow £3,210 for electric lighting extensions. There was considerable opposition.

Miscellaneous

AUSTRALIA.—The Representative in London of the Commonwealth of Australia (Captain R. Muirhead Collins, C.M.G.) has, says the *Board of Trade Journal*, received tender-forms, specifications, &c., in connection with the supply and delivery of two multiple magneto switchboards required by the Postmaster-General's Department, Sydney. Tenders will be received at the office of the Deputy Postmaster-General, Sydney, until May 19th.

BARROW-IN-FURNESS.—The Corporation invite tenders for the supply of electrical stores during the year ended March 31st, 1910. Particulars from the Electrical Engineer, and tenders by March 1st.

BELFAST.—Stores are required by the Tramways and Electricity Committee. Tenders to the Town Clerk by March 8th. (See an advertisement this week.)

COLCHESTER.—Tenders for stores by March 3rd are invited by the Tramways Committee.

CORK.—Tenders are invited by March 4th for the lighting of certain portions of the Cork Rural District Council by electricity, gas, or other illuminant during the period of ten years from September 1st, 1909. Particulars from the Clerk, the Board Room, Cork Workhouse.

DUNDEE.—The Tramways Committee require tenders by March 6th for stores.

EAST COWES.—A 30 h.p. electric motor and transmission gear is required at the Council's waterworks. Particulars from the Engineer, and tenders by Feb. 27th.

HESTON & ISLEWORTH.—Tenders are invited for stores during the year ended March 31st, 1910, including meters, cables, troughing boxes, &c., and sundry electrical supplies. Tenders to the Clerk by March 3rd.

Digitized by Google

ILFORD.—The Council invite tenders for electric meters for registering the current consumed by their tramcars. Particulars from the Clerk, and tenders by March 8th.

ITALY.—The municipal authorities of Marino have, says the *Board of Trade Journal*, on the authority of an Italian exchange, voted in favour of electrifying the present railway, which will be extended to Rome, where a station will be built at the Via Principe Amedeo.

LONDON: *Fulham.*—General and electrical stores are required by the Council. Tenders by March 4th.

NETHERLANDS.—Messrs. Löben Sels and van den Berg have, says the *Board of Trade Journal*, applied to the municipal authorities of Loosduinen for a concession for the construction of an electric tramway from Scheveningen to Hoek van Holland through Kijkduin, with a branch from Kijkduin to Delft through Loosduinen.

RICHMOND (IRELAND).—The Committee of Management of the Richmond Asylum invite tenders for stores during the twelve months from April 1st, including electrical supplies. Particulars from the Clerk, Grangegorman Annexe, Dublin, and tenders by March 16th.

SWANSEA.—The Guardians have resolved to instal their own private telephone system, and to dispense with that of the National Telephone Co. It is proposed to connect the workhouse, the medical officer's residence, and the Union offices at an estimated cost of £100. The annual cost of the system will be £35, and it is anticipated that this will result in a saving of £30 per annum.

WREXHAM.—The Town Council invites tenders by March 13th for cables, cable jointing requirements, service cut-outs, meters, incandescent lamps, arc lamp carbons, lubricating oils, coal, wood troughing, &c., boiler solution.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

PROVINCES.

ALDERSHOT.—Secondary school (£3,000). T. C. Uren, Town Hall, Aldershot.

BOGNOR.—Alterations, Isolation Hospital (£3,000). P. A. Bridge, Borough Surveyor, Bognor.

BRIDLINGTON.—Palm house (£1,500). Architect, E. R. Matthews, Council Offices, Bridlington.

School. Architect, Mr. Forrest, Moot Hall, Newcastle-on-Tyne.

BELFAST.—Banking Premises, Ulster Bank, Ltd. Architects, Blackwood & Jury, 41 Donegal Place, Belfast.

BLACKPOOL.—Infants' school (£6,000). J. S. Brodie, Borough Surveyor, Blackpool.

CROYDON.—Beulah Road, Mitcham Road, Oval Road, and Sydenham Road schools are to be wired, &c., at an estimated total cost of £420.

COLWYN BAY—Public buildings (£40,000). Architects, Clegg & Son, Spring Gardens, Manchester.

DUBLIN.—Additions, Queen's Theatre (£5,000). Architect, R. Stirling, 24 Clare Street, Dublin.

Warehouse, British & Irish Steam Packet Co. Architects, Byrone & Co., Suffolk Street, Dublin.

ERDINGTON.—Offices and library. W. Humphries, Council House, Erdington.

FROME.—School, Milk Street (£3,500). Architect, A. B. Cottam, Bridgwater.

FLEETWOOD.—Theatre. Architect, Albert Winstanley, Temple Chambers, St. Anne's-on-Sea.

HEREFORD.—Secondary school. Architect, R. A. Jack, Shire Hall, Hereford.

KING'S NORTON.—Additions to hospital, West Heath. W. Cross, Surveyor to Council.

LISCARD (Cheshire).—Additions, High School (£4,000). Architect, J. L. Hughes, 10 Victoria Street, Liverpool.

NEWCASTLE.—Head Post Office (£20,275). Builders, Kirk & Brown, Byker Bridge, Newcastle.

PORTSMOUTH.—Additions to Jewish Synagogue (£1,247). Architects, Roke and Cogswell, Prudential Buildings, Commercial Road, Landport.

PLYMOUTH.—Church, St. Symons. Architect, H. Reed, Castle Street, Exeter.

Church, St. Augustine. Architects, King & Lister, 8 Princess Square.

RAWMARSH (Yorks).—Isolation Hospital. Architect, J. Bourne, Rawmarsh (Yorks).

SOUTH SHIELDS.—Church (£3,500). Architect, H. Griers, South Shields.

Additions, workhouse (£5,000). Architect, J. H. Morton, 50 King St., South Shields.

SWANSEA.—Lunatic Asylum, Town Hill. J. Thomas, Town Clerk, Swansea Town Council.

TENDERS RECEIVED AND ACCEPTED

BARKING.—The Council has accepted the tender of the Western Electric Co. for feeder cable at £46. Six tenders were received, ranging from that stated to £57 0s. 7d.

LONDON: *London County Council.*—The tender of Mr. Jean Schmidt (the licensee and sole representative of the Oil & Waste Saving Machine Co., Ltd.), amounting to £209, for the supply of oil and waste saving machinery for use at the central car repair depôt, is recommended for acceptance.

Lewisham.—The tender of Macdonald, Syer & Co., Ltd., at £7 10s. has been accepted by the Council for the substitution of electricity for gas in the mortuaries and post-mortem rooms in connection with the Coroner's Court at Ladywell.

Hammersmith.—The following tenders have been received for a 2,000-kw. steam turbo-generator: Richardson, Westgarth & Co., £5,470; Parsons & Co., £5,473; Siemens Bros., £5,473; Richardson, Westgarth & Co. (provisionally accepted), £5,613; Bellis & Morcom, Ltd., £5,616; the Brush Electrical Engineering Co., £5,695; Fraser & Chalmers, £5,850; British Thomson-Houston Co., £5,900; General Electric Co., £5,930; British Westinghouse, £6,060; Electric Construction Co., £6,400; J. Howden & Co., £6,491; Vickers, Sons & Maxim, £6,722; John Musgrave & Co., Ltd., £6,805; Maschinen Fabrik Oerlikon, £6,995; Lahmeyer Electrical Co., £7,091; Willans & Robinson, £7,220. All the firms, with the exception of the Brush Electrical Engineering Co., British Thomson-Houston Co., British Westinghouse Co., Maschinen Fabrik Oerlikon, Lahmeyer Electrical Co., and Willans & Robinson, submitted several alternative prices. The lowest of these in each case has been inserted. For a motor-driven exciter twelve tenders were received, ranging from £218 to £417. The tender of the General Electric Co. at the former price has been provisionally accepted. For the supply and erection of condensing plant the tenders were as follows:—Willans & Robinson, vacuum augmenter (provisionally accepted), £1,173; Fraser & Chalmers, £1,335; Cole, Marchment & Co. (per B.T.-H.), £1,355; Brush Electrical Co., £1,378; Worthington Pump Co. (per B.T.-H.), £1,430; W. H. Allen, Sons & Co. (per B.T.-H.), £1,550; Belliss & Morcom, Ltd. £1,598; Midland Engineering Co., £1,601; Willans & Robinson (Contraflo), £1,617; Mirrlees, Watson & Co., £1,705; Leblanc (per British Westinghouse), £1,720; Parsons & Co., £1,846; Richardson, Westgarth & Co., £1,880; J. Musgrave & Son, Ltd., £2,014.

The tender of the British Electric Transformer Co. for two 400-kw. transformers to transform from 2,500 to 5,000 volts has been provisionally accepted at £278, and that of the same company for two 250-kw. air-cooled single-phase transformers at £184 each. [By an error in our last issue we stated that these tenders had been accepted by the West Ham Corporation.]

Marylebone.—The Council has received the following tenders for house service boxes required in connection with the conversion from gas to electric lighting in the streets:—Callenders Cable & Construction Co., Ltd., No. 1, 6s. 4d.; No. 2, 7s. 3d.; No. 3, 7s.; No. 4, 7s. 9d. each. Johnson & Phillips, Ltd., fittings for No. 1, 1s. each; twin ditto, 10d. each. British Insulated & Helsby Cables, Ltd., twin fittings for No. 2, 1s. 1½d. each. Sykes & Sugden, Ltd., fittings for No. 2 and 3, 1s. 9d. each; No. 4, 1s. 11d. each.

St. Pancras.—The Council received the following tenders for the supply of a motor-generator for mains testing:—British Thomson-Houston Co., Ltd., including field rheostat (accepted), £52; Crompton & Co., Ltd., including field rheostat, £60 17s. 6d.; Lahmeyer Electrical Co., Ltd., including switchgear, £165 6s.

Wandsworth.—The following tenders were received by the Council for the electric light installation at the Putney Library:—Donnison, Sillem & Co., £95 15s. (accepted); Grosvenor Electrical Co., £125 18s.; H. Dakin & Co., £125 19s.

LOWESTOFT.—Contracts have been placed with Messrs. Siemens Bros. & Co., and Messrs. Venner & Co., for the supply of meters during the next twelve months.

WEST HAM.—The tenders for transformers referred to on p. 165 of our last issue should have been under Hammersmith and not West Ham.

WIGAN.—The following tenders have been accepted, among others, for electrical stores:—Accessories: General Electric Co., E.M.F. Mfg. Co., Dorman & Smith. Lamps: General Electric Co. Cables: W. T. Glover & Co., Ltd., British Insulated & Helsby Co. Tramway Accessories: Dick, Kerr & Co., Ltd., P. R. Jackson & Co., British Westinghouse Electric Co., Watlington & Co., British Insulated & Helsby Cables, Ltd., Flemming, Birkby & Goodall, Dick, Kerr & Co., British Thomson-Houston Co. Overhead Material: British Insulated & Helsby Cables, Ltd., Watlington & Co., and General Electric Co.

YORK.—The D.P. Battery Co., Ltd., have received an order from Messrs. Rowntree & Co. to instal in their Cocoa Works at York an L.S.H. type battery with a capacity of 323,000 watt hours, also an automatic reversible booster and switchboard to deal with the fluctuations of the load. A special feature of the power plant at these works is that it consists of two interconnected stations, 330 yards apart, one gas and the other steam driven.

Digitized by Google

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night was £59 5s. to £59 15s. per ton (£61 to 61 10s. last week).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Headlands' Patent Electrical Storage Battery Co., Ltd., is to be wound up voluntarily.

A meeting of the Automatic Electrical Advertising Syndicate, Ltd., will be held at 26 Victoria Street, Westminster, S.W., on March 18th, at 12 p.m., to hear the liquidator's report of the winding up.

The trustee in the bankruptcy of E. A. Gresham, electrical engineer, of Leeds, has been released.

The trustee in the bankruptcy of E. N. Owen, electrical engineer, of 2 Yale Court, Hampstead, London, has been released.

The creditors of the British Eastern Electric Power Co., Ltd., are requested to send particulars of their claims to the Liquidator, Mr. T. F. Stevens, 57½ Old Broad Street, London, E.C., before April 7th.

DISSOLUTION OF PARTNERSHIPS.—The partnership between Arthur Howe and L. F. Humbert, Electrical Engineers, 3 & 4 Alt Grove, Wimbledon, has been dissolved.

The partnership between W. White, T. H. Bacon, and C. J. Baker, Electrical Engineers, 3 Budge Row, Cannon Street, London, E.C., has been dissolved.

ALUMINIUM CORPORATION.—The adjourned statutory meeting of the creditors of the Aluminium Corporation, Ltd. (in liquidation), was held on Wednesday last week in London. After consideration of schemes put forward by the creditors and by the company, a resolution was passed that application should be made to the Court for a liquidator to be appointed on behalf of the creditors in place of the joint liquidators appointed by the company.

D.P. BATTERY CO.—To cope with their annually increasing output of storage batteries, this company have reorganised and extended their works, already covering some 5 acres, but reserving 10 acres for future requirements. The additional large forming shop, recently completed, affords facilities for increasing their output by some quarter million of plates annually, which, with the large stock of over 20,000 plates of standard types, will enable the company to give prompt delivery. A special feature in the works is their test-room and laboratory, in which a most careful supervision is exercised over the products in the various states of manufacture and in the analysis of all metal used.

CHANGE OF ADDRESS.—The address of Siemens Bros. Dynamo Works, Ltd., is now Caxton House, Westminster, London, S.W. Telephone No., Gerrard 860.

EXTENSION OF PREMISES.—In spite of the general trade depression, the business of the Armorduct Manufacturing Co., Ltd., of Farringdon Avenue, London, E.C., continues to extend, and it has been found necessary to take up additional accommodation in the present building.

AGENCIES.—The Piggott Electrical Co., of 24 New Bridge Street, London, E.C., have been appointed sole London agents for Messrs. Smith Bros'. specialities of cables, flame arc lamps, enclosed arc lamps, arc lamp carbons, incandescent lamps, and electrical accessories, and will carry a large London stock. The firm still continue their other agencies.

CAMBRIDGE SCIENTIFIC INSTRUMENT CO.—This company have taken over the sole rights of sale and manufacture, outside the American continent and Germany, of the thermometers, gauges, &c., of the Hohmann & Maurer Manufacturing Co. of London and Rochester, N.Y., U.S.A., and the regulators of the H. & M. Automatic Regulator Company of Rochester. Mr. Coppard, who represented the Hohmann & Maurer Co. in the past, has been transferred. All communications with reference to these goods, which were formerly sent to 98 Clerkenwell Road, London, E.C., should now be sent to the Cambridge Scientific Instrument Co., Chesterton Road, Cambridge.

SUNBEAM LAMP CO.'S WHIST DRIVE.—The staff and employees of the Sunbeam Lamp Co., Ltd., indulged in a whist drive and dance on Thursday. The Beaconsfield Hall, Gateshead-on-Tyne, where the gathering took place, was brilliantly illuminated by types of the company's latest lamps.

Proposed Engineering Exhibition at Manchester.—In our issue for January 21st, p. 77, we gave particulars of a proposed Engineering Exhibition at Manchester. We now learn that at a representative and influential meeting, held at the Midland Hotel, Manchester, on February 17th, Mr. W. T. Stubbs (Messrs. J. Stubbs, Ltd.) in the chair, it was resolved: "That this meeting approves of a general Engineering and Allied Trades Exhibition being held in Manchester during the autumn of 1910, on the lines laid down by the International Trade Exhibitions, Limited, London." It was also resolved: "That the provisional committee be reappointed, with power to add to their number."

MISCELLANEOUS CITY NOTES

WINNIPEG ELECTRIC RAILWAY CO.—Subscriptions were invited last week for an issue of £300,000 4½ per cent. perpetual consolidated debenture stock, which will be secured by a trust deed in favour of the British Empire Trust Co., Ltd. The new issue is required for the general development of the company's undertaking.

RIO DE JANEIRO TRAMWAYS LIGHTING POWER CO.—A special meeting is to be convened for the purpose of authorising an increase of the capital of the company.

SOUTHERN ELECTRIC TRAMWAYS CO. (BUENOS AYRES).—A new issue of capital in the form of £100,000 5 per cent. first mortgage debentures has been advertised during the week.

MARCONI'S WIRELESS TELEGRAPH CO.—In consequence of the pressure of work, Colonel Sir Charles Euan Smith, K.C.B., is relinquishing the position of chairman, but will retain his seat upon the Board. Mr. G. Marconi will succeed to the chairmanship.

HURST, NELSON & CO.—An issue of 20,000 6 per cent. accumulative preference shares of £10 each at par is announced. Of these, 4,636 shares had already been applied for at the time of the issue of the prospectus.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO.—A final dividend of 7 per cent. per annum for the half-year ended December 31st last is recommended on the ordinary shares.

COUNTY OF LONDON ELECTRIC SUPPLY CO.—The directors recommend a final dividend on the ordinary shares of 6 per cent. per annum, less income tax, for the half-year ended December 31st, 1908, making 5 per cent. for the year. The sum of £16,000 has been placed to reserve for depreciation and about £3,700 carried forward.

LA PLATA ELECTRIC TRAMWAYS CO.—Subscriptions are invited for 170,000 six per cent. cumulative preference shares of £1 each.

The Physical Society.—At the Annual General Meeting of the Physical Society, held on October 12th, the following officers and council were elected for the ensuing year: *President*, Dr. C. Chree, F.R.S. *Vice-Presidents*, those who have filled the office of President together with Mr. W. Duddell, F.R.S.; Prof. A. Schuster, F.R.S.; Mr. S. Skinner; and Dr. W. Watson, F.R.S. *Secretaries*, Mr. W. R. Cooper and Dr. S. W. J. Smith. *Foreign Secretary*, Prof. S. P. Thompson, F.R.S. *Treasurer*, Prof. H. L. Callendar, F.R.S. *Librarian*, Dr. W. Watson. *Other Members of Council*, Mr. A. Campbell, Dr. W. H. Eccles, Dr. A. Griffiths, Dr. J. A. Harker, Prof. C. H. Lees, F.R.S.; Mr. T. Mather, F.R.S.; Dr. A. Russell, Prof. E. Rutherford, F.R.S.; Mr. F. E. Smith, and Mr. R. S. Whipple. The President delivered an address which dealt principally with the comparison of records of terrestrial magnetism.

Wireless Telegraphy and Telephony.—The House of Representatives at Washington passed a Bill last week, requiring that all ocean-going ships leaving American ports which carry passengers shall be equipped with wireless telegraphy apparatus. It has been urged in this connection that any legislation by Congress shall allow for the substitution of wireless telephony for wireless telegraphy on the Great Lakes.

In extension of the order placed by the Brazilian Government with Marconi's Wireless Telegraph Co., Ltd., for the equipment of fourteen war-vessels, now in course of construction in British yards, the company has received an order from the Hydrographic Department to equip four land stations near Rio de Janeiro. The main station in Rio de Janeiro will be connected directly with Guaratiba, Ponta Negra, and Ilha Raza, the equipment at the latter place being suitable for communication with vessels at sea up to a distance of some 350 miles. The company has also received orders from the White Star Steamship Co. to equip three more of their ships. This is in addition to the eleven installations already carried by the fleet. The Norddeutscher Lloyd Co. now have seventeen Marconi installations on their Atlantic fleet.

A statement was made in Parliament on Monday by Mr. Churchill, President of the Board of Trade, to the effect that he was considering the advisability of introducing legislation requiring all British-owned ocean-going steamships to carry efficient wireless telegraph equipments.

In a lecture before the Engineering Society of the Birmingham University on Thursday last, Sir Oliver Lodge summarised the history of wireless telegraphy and telephony, beginning with Lord Kelvin's work on electric oscillations in 1853. Hertz experiments with electric waves in 1888, and the lecturer's own work in tuning in 1890 were briefly referred to. In 1894 Sir Oliver had demonstrated signalling by means of a coherer, and the successful application of this experimental work to commercial telegraphy was accomplished by Mr. Marconi in 19[illegible] and the following years. Finally, the lecturer gave a summary of the results obtained by the Lodge-Muirhead system, with particular reference to its high tuning capabilities.

Digitized by Google

APPOINTMENTS AND PERSONAL NOTES

Mr. W. J. Draffin, senior tramway inspector at Hull, whom the Doncaster Tramways Committee appointed last week as chief inspector on the borough tramway system, has decided not to accept that appointment. The post has now been offered to Mr. Francis Craggs, at present chief inspector under the Sunderland District Electric Tramways, Ltd.

Mr. G. W. Fenton, an Assistant Engineer at the Aberdeen Corporation Electricity Works, has been presented with a kit-bag on leaving to take up the post of Manager to the Aberdeen Ice Company.

Mr. F. E. Andrews has been elected Chairman of Messrs. Bruce, Peebles & Co., Ltd., and Mr. Lee Murray General Manager.

The Rochdale Electricity Committee recommend that the salary of their Electrical Engineer, Mr. C. C. Atchison, should be increased by £50 per annum, bringing it up to £400 per annum.

Applications are invited by March 4th, for the position of Chief Electrical Engineer to the Gloucester Corporation electricity undertaking.

Applications are invited by March 3rd for the post of Electrical Engineer and General Manager of the electrical undertaking of the St. Marylebone Borough Council. Salary, £600 per annum.

It is stated that Herr von Podbielski, the former Prussian Minister of Agriculture, has joined the staff of an important electrical company in Germany. His work is said to consist in pressing the claims of the application of electricity to all branches of agricultural work.

The Highways Committee of the London County Council make the following recommendations in regard to members of the tramways staff:—(*a*) That the salary of Mr. J. K. Bruce, traffic manager, be increased from £850 to £900, from and including April 1st, 1909, and subsequently to £1,000 a year, by two annual increments of £50. (*b*) That the salary of Mr. J. Welling, permanent way engineer, be increased from £500 to £550 a year. (*c*) That the salary of Mr. H. D. Smith, advertising assistant, be increased from £500 to £525 a year. (*d*) That the salary of Mr. W. E. Ireland, rolling stock superintendent, be increased from £400 to £450 a year. (*e*) That the salary of Mr. E. Cloney, district traffic superintendent, northern section, at present in receipt of £230 a year, rising by two annual increments of £10 each to £250 in October, 1910, be increased to £250 a year.

Refusal of a Patent for the Manufacture of Metal Filaments.—In June, 1906, the Deutsche Gasglüchlicht Akt.-Ges. (Auergesellschaft), the makers of the Osram lamp in Germany, applied for a British patent for a process in the manufacture of metal filaments, which consisted in sintering the filament together, in the presence of an inert gas, by passing a continuous current through the filament instead of an alternating current, as was usual. When the latter was employed, it was stated to cause deformation of the filament so long as the operation was not carried out in a vacuum. The grant was opposed by Dr. Hans Kuzel, on the ground that the invention had been previously patented in this country. In the first place the grant was allowed; on appeal, however, the grant was refused on the ground that the alleged invention was merely the selection of the better of the two known methods of carrying out a process, namely, the selection of continuous current in preference to alternating current for the process of sintering. The Attorney-General, who heard the appeal, ruled that the selection of the best conditions for a process may not be subject-matter for a patent when the process has been previously patented. The appeal was heard last October, but the result is only now made public.

London County Council Staff Inventions.—The Highways Committee of the London County Council report having had under consideration the question of the course to be taken with regard to inventions and improvements effected by officials of the Council in connection with the Council's tramways. Cases have occurred in which an improvement designed in the tramways department has been patented by contractors, and in some cases the Council, when purchasing additional articles affected by such patent rights, has been asked to pay a royalty thereon. Whenever letters patent have been taken out by an official of the Council, it has been the usual practice for the Council to have the unfettered right of user of the articles patented, and it is thought that steps should be taken to ensure that the Council should not have to pay any royalty on inventions or improvements effected by officials of the Council, but in respect of which letters patent may be acquired by some other person or body. This object, continues the report, would be secured by effectually publishing the inventions. This course was adopted by the Council in respect of specially devised ladders on fire-brigade motor (escape) vans. It is not intended that this arrangement should in any way restrict the liberty of an official who may desire to obtain protection for an invention under standing order No. 274. The Committee therefore recommend that this course should be adopted.

COMPANIES' MEETINGS AND REPORTS

NOTTING HILL ELECTRIC LIGHTING CO.—The report of 1908 states that the capital expenditure has been increased during the past year by £4,216. The number of consumers is now 2,846, and over 98 per cent. of these are supplied at 200 volts. The gross revenue for the year was £38,902, an increase of £847, and the total net profit was £19,484. Deducting depreciation, renewal and reserve fund, debenture and other interest, there is a balance available of £10,908. The usual dividend of 6 per cent. (less income tax) on both the preference and ordinary shares is recommended, and the balance will be divided in accordance with the Articles of Association, one-half being credited to the founders' shares, and the other half to the ordinary and preference shares. This will enable a further 1 per cent. to be paid on both ordinary and preference, with a distribution of £3 per share on the founders' shares. The meeting is on March 2nd.

VICTORIA FALLS POWER CO.—The report of the British South African Co. for the year to March 31st, 1908, states that the Victoria Falls Power Co. has now nearly completed the erection of two new steam-driven electrical stations upon the Witwatersrand, and is already delivering power to the mines from a portion of the new plant. It has lately entered into an important contract for the supply of the whole of the power requirements (15 mines) of the Rand mines and Eckstein groups, and other contracts are under negotiation. In order to carry out these contracts large additional installations of plant will be required, the funds for which are to be provided by the issue of further debentures and preference shares.

At an extraordinary general meeting last week, it was agreed to alter the name of this company to "The Victoria Falls and Transvaal Power Co., Ltd."

ABERDEEN SUBURBAN TRAMWAYS CO.—The accounts for the half-year ended January 31st, 1909, show a net profit of £662, which it is recommended should be carried forward. The amount standing to the credit of profit and loss account is now £1,418.

CHARING CROSS, EUSTON & HAMPSTEAD RAILWAY CO.—At the meeting on Thursday the report and accounts given in our issue for February 11th, were adopted.

MEXICAN LIGHT & POWER CO.—At the annual meeting which was held on the 17th inst., the directors nominated for the new board, a list of whom was given in our issue for January 28th, were elected. Dr. F. S. Pearson is president.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO.—At the meeting held on Thursday, the report and accounts given in our last issue were adopted. Mr. W. F. Fladgate, the chairman, who presided, spoke at some length upon the difficulties which the electric lighting industry had had to suffer from during the past four years, in consequence of the London Electric Power Bills, and expressed his pleasure at the fact that this question had now been definitely settled. It was agreed that the directors' fees should be increased from £1,500 to £2,500 per annum.

NORTH-WEST LONDON RAILWAY CO.—At a special meeting last week, the company's Bill, which proposes to construct the portion of their line between Edgware Station and Brondesbury, practically as an extension of the Baker Street and Waterloo Railway, was approved.

BAKER STREET & WATERLOO RAILWAY CO.—At the meeting on Thursday the report and accounts given in our last issue were adopted. Sir George Gibb, who presided, pointed out that the dividends were provided for out of the net revenue of the company, and that there was not now any necessity for a payment by the Underground Electric Railways Company of London, as had been the case last year. At a subsequent special meeting the Bill for providing additional lifts at Oxford Circus Station, and abandoning the subway works in Trafalgar Square, authorised in 1905, was approved.

BEYER, PEACOCK & CO.—At the annual general meeting last week the Chairman, Sir Vincent Caillard, pointed out with regard to the item of "electrical machinery written off, £1,500," that the company, owing to the very favourable terms upon which they could purchase electrical energy from the Manchester Corporation, found it paid them to scrap the electrical machinery they had and to write off the cost over a period of years.

SIMPLEX CONDUITS.—The annual general meeting of Conduits, Limited, was held in Birmingham last week. The profits of the year amount to £12,921, and, after charging directors' fees, depreciation, and income tax, and adding the amount brought forward from last year, there remains for disposal £13,131. The 6 per cent. preference dividend absorbed £2,280, and interim dividend on ordinary shares to June 30th, 1908, at the rate of 7½ per cent. per annum, £15,000. £4,000 is again carried forward to reserve fund, and, after allowing £2,500 for final dividend on ordinary shares at 12½ per cent., making 10 per cent. for the year, £2,747 is carried forward.

BRITISH ELECTRIC TRANSFORMER CO.—After meeting all expenses, there remains a net profit of £11,528 for 1908, which, with the amount brought forward from last year, makes a total available balance of £11,563. The directors recommend carrying to reserve account £3,000, writing off preliminary expenses £1,266, payment of preference dividend of 6 per cent.

Digitized by Google

for two years ended December 31st, 1908, £3,747, payment of a dividend of 3½ per cent. on the ordinary shares £2,428, and to carry forward a balance of £1,119.

WIRRAL RAILWAY CO.—At the half-yearly meeting on Tuesday, the chairman stated that a good deal of pressure had been brought upon the directors to convert their line to electric traction, but they were not yet in a position to do so.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING CO.—The report for 1908 states that after providing for the amount placed to renewal account (£8,793), and after paying the dividends on the 6 per cent. first preference shares to June 30th, 1908, on the 5 per cent. second preference shares to September 30th, 1908, and an interim dividend at the rate of 8 per cent. per annum on the ordinary shares for the first half of the year, there is a balance of £8,165. The sum of £1,500 has been appropriated to the payment of the first preference dividend to the end of the year, and £625 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date. It is proposed to pay a further dividend on the ordinary shares at the rate of 8 per cent. per annum, making 8 per cent. for the year, leaving a balance of £1,840 to be carried forward. The meeting is on March 4th.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS.—The report for the year to January 31st shows a profit of £8,935 after deducting all expenses and interest on calls received in advance. After writing off a proportion of the preliminary and formation, and transferring £2,000 to depreciation, there is a sum of £5,844 remaining, out of which a dividend of 7 per cent. is recommended, carrying forward £913.

At the second annual meeting last week, the report and accounts were adopted. Mr. J. B. Simpson, who presided, said that the capacity of the company's plants was 10,600 h.p., and another two with a capacity of 4,600 h.p. were just starting. There were 120 coke oven batteries in Northumberland, Durham, and North Yorkshire, not to mention blast furnaces and other sources of waste heat, and the difficulty of concentrating this waste power had now been overcome. The power companies on the north-east coast had now made arrangements to take in bulk the whole of the power that the waste heat stations were capable of turning out, the power companies bearing the cost of operating these stations and keeping them in repair, and paying also a rental and a price for the power. Thus the expenses of the company were few, and the power companies found it to their advantage to do this, for the cost of generating was less than in their steam stations.

ELECTRIC SUPPLY CORPORATION.—The report for the year ended December 31st, 1908, states that the gross revenue amounted to £21,239, as against £16,741 in the previous year. The sum brought into net revenue account as a result of the year's working amounts to £6,566 made up as to £6,335 from the company's supply business, and as to £230 from a dividend received from the Dumbarton Tramway preference shares, compared with £5,456 in the preceding year, made up as to £4,262 from the company's supply business, and as to £1,194 from the tramways and various payments received in connection therewith. After meeting debenture interest and interest on temporary loans there remains a surplus of £2,397, as compared with the balance, £401, in 1907.

At the meeting on Thursday the report and accounts were adopted.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—The report for the year 1908 states that the connections now aggregate the equivalent of 985,159 8-c.p. lamps (=31,525 kw.) against 929,579 8-c.p. lamps in 1907. After allowing for depreciation, sinking fund, and other charges, the net balance is £46,250, from which must be deducted the second half-year's dividend on the preference shares, leaving a balance of £37,564. Out of this the Board recommend the payment of a dividend at the rate of 10 per cent. per annum, less income tax, for the past half-year, carrying forward a balance of £11,439.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY CO.—The accounts for the half-year ending December 31st, 1908, state that the capital expenditure during the half-year amounted to £43,000, of which details appear in Account No. 5. The gross receipts amounted to £143,234, being an increase of £23,963, or 20·09 per cent. on the receipts for the corresponding half of 1907. The working expenses amounted to £72,468, being an increase of £1,715, or 2·43 per cent. After providing for interest and other items and for dividend at the rate of 4 per cent. per annum on the amounts paid up on the preference shares, there remains a balance of £23,448 available for dividend on the ordinary shares, and the directors recommend that a dividend at the rate of ¾ per cent. per annum be declared on the amount paid up on the ordinary shares, leaving a balance of £5,859 to be carried to next half-year's account. The number of passengers carried was 16,990,501, compared with 13,914,779 in the corresponding period of last year; the average receipt per passenger was 1·94d., compared with 1·98d.; and the train mileage was 1,147,388, compared with 952,571.

At the half-yearly meeting on Thursday the report and accounts were adopted. Sir George Gibb, who presided, said that the position of the company now was that the debenture interest was secured, and the dividend on the ordinary shares seemed certain to be a constantly increasing one.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—The report for the half-year to December 31st, 1908, shows gross receipts of £3,734, being £157 in excess of those of the corresponding period of last year. After providing for debenture interest there is an available balance of £1,122, out of which the directors recommend the payment of the usual half-yearly dividend on the 5 per cent. preference shares; that £150 be paid to the contractors on electrical equipment account; and that the balance of £497 be carried forward to next half-year as against £512 carried forward from the corresponding period of the previous year. A resolution will be moved at the half-yearly meeting of shareholders, to be held on February 18th, to enable the directors if they shall so think fit, and upon such terms and conditions as they may approve, to enter into a lease for the working of the proposed extension (when made by an independent company) of the line from Lucan to the Spa Hotel, the construction of which has been authorised by a recent Order in Council.

The report and accounts were adopted at the meeting on Thursday. The resolution with regard to the extension referred to above was passed.

GIANT'S CAUSEWAY ELECTRIC TRAM CO.—The annual meeting was held at Portrush on Thursday. The report showed a net profit of £1,276, against £788 in 1907.

NATIONAL TELEPHONE CO.—The revenue for the December half-year amounted to £1,498,431, compared with £1,387,189 for the corresponding period of 1907. The working expenses amounted to £858,566, compared with £780,352. The net result (after deducting the Post Office Royalties amounting to £144,226) is a profit balance of £495,638, as compared with £474,235, an increase of £21,402. A dividend of 6 per cent. per annum is recommended on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock, less income tax in all cases; the sum of £155,000 is transferred to reserve, and the balance of £10,338 carried forward. The meeting is on the 25th inst.

UNDERGROUND ELECTRIC RAILWAYS COMPANY OF LONDON, LTD.—The report for the year ended December 31st, 1908, states that the revenue account shows, after payment of interest on the 4½ per cent. bonds of 1933, a deficit of £11,836. To cover this deficit Messrs. Speyer have paid, in accordance with the agreement of April 7th, 1908, to the company the sum of £12,000, in respect of which there has been issued to them £8,000 4½ per cent. bonds and £12,000 6 per cent. income bonds. Electric power continues to be furnished to the Metropolitan District, the Baker Street and Waterloo, the Great Northern Piccadilly and Brompton, and the Charing Cross Euston and Hampstead Railway Companies, as well as to a section of the London United Tramways. The net output of electric energy from the power house during the half-year was 57,513,700 kilowatt hours.

YORKSHIRE ELECTRIC POWER CO.—The report and accounts given in our last issue were adopted at the meeting on Feb. 16th. Mr. Arnold G. Lupton, the Chairman, who presided, said that the most important point to be placed before the shareholders was that the company had now begun to work off the adverse balances from the first years of construction and development. With regard to the utilisation of waste heat gases from blast furnaces and coke ovens, to which much attention was now being directed, the directors, he said, had been watching this, and it was possible that they might soon develop this source of power.

Sub-station Fatality.—On Thursday last an attendant named J. C. Tickle, in charge of the sub-station of the London Electric Supply Corporation at Bloomfield Place, New Bond Street, was killed by electric shock. One of the transformers had been found faulty, and the deceased received the shock when attempting to disconnect the transformer. He was a competent man, with technical knowledge, but should not have attempted to disconnect the transformer without instructions from the sub-station superintendent. The pressure on the H.T. side was 2,500 volts. At the inquest on Saturday a verdict of accidental death was returned.

Telegraph Traffic.—The El Arich route was down on February 18th between Adana and Beyreuth, and also between Diarbekir and Beyreuth. On the same day communication between Rome and Constantinople was interrupted. Further interruptions occurred to the former route on the following day between Ayzgat and Diarbekir, and also between Konia and Adana, while the wire between Rome and Constantinople was restored to working order. The submarine cable between Oran and Tangier ceased operating on the 20th inst., and on the 22nd inst. the El Arich route was repaired. Since the 18th inst. it has not been possible to reach French Guiana and Brazil by the French Cable Co.'s route *via* Hayti, which means that the cable between Martinique and Paramaribo is broken. The cable between Seattle and Sitka has ceased working, and telegrams for Alaska will be sent *via* Ashcroft. The cable between Sitka and Valdez, which, it was stated, was broken by a submarine disturbance, has not yet been repaired.

"Electrical Engineering," although the Cheapest Electrical Paper (Price 1d. weekly), contains the Most Useful and Practical Articles, the Best Illustrations, and the Latest News. It is read by the Leading Electrical Engineers, and is regarded as a Reliable Authority in all matters connected with the Electrical Industry.

SUMMARY

A 16-CANDLE-POWER 100-volt Osram lamp has been placed on the market in Germany, and a similar lamp has been produced by the Wolfram Lampen Akt. Ges. General reductions in the price of some of the larger sizes of metal filament lamps have been made by many firms in that country. (Page 202.)

AT the General Electric Co.'s staff dinner on Saturday, Mr. G. Byng expressed the view that free trade was the cause of Great Britain having lost its leading place in the electrical industry, and Mr. Mordey contended that Great Britain was still leading. (Page 202.)

IN a Paper read informally before a meeting of members of the Newcastle Local Section of the Institution of Electrical Engineers, Mr. A. P. Chalkley reviewed the subject of the electrical equipment of ships, giving notes on supply voltages and circuits, generating plant, switchgear, and various applications of power. (Page 203.)

IN his report upon the London County Council tramway accounts for the year 1907-8, the District Auditor, Mr. T. B. Cockerton states that in establishing a renewals fund and a general reserve fund, the County Council seem to be making provision over and above that required by statute. He, however, approves of this policy, owing to the uncertainty as to whether the life of various assets will be as long as the loan period. The District Auditor concludes by saying that as far as the accounts show, the Council's tramways appear to be worked on a very sound financial basis, and that all contingencies which are likely to arise seem to be adequately provided for. (Page 204.)

THE vacuum cleaner has been successfully applied to the cleaning of boiler flues and economisers. (Page 204.),

A FORM of high-tension switchgear, in which the oil switches, &c., can be withdrawn complete for inspection on wheeled carriages has been developed by the Felten & Guilleaume—Lahmeyerwerke Co. The arrangement is particularly suitable for mining distribution boards and other conditions where space is limited. (Page 205.)

IN an illustrated description of the new "Midland" telephone exchange in Birmingham, details are given

Digitized by Google

of an improved method of party-line working. Each party line has two jacks on every multiple, the connections to one of which are reversed on the I.D.F., so that the party-line subscribers may be rung with the ordinary ringing key. (Page 206.)

The Dublin Electricity Committee differ from the opinions expressed in the recent report by the City Treasurer and City Accountant upon the electricity undertaking, and express their confidence in the business.—A special meeting of the London County Council is to be summoned to consider the purchase of the lines belonging to the London United Tramways, Ltd., which are in the county.—The question of a bulk supply of electricity is being considered by the Bethnal Green Borough Council.—Efforts at a compromise with the National Electric Construction Co. are recommended by the General Purposes Committee of the Oxford Corporation.—All the local authorities affected by the proposed tunnel and electric railway under the Tyne have now withdrawn from any financial participation in the scheme.—Negotiations are in progress between the Willesden Council and the North Metropolitan Electric Power Supply Co. for a rearrangement of the charges for bulk supply by the company. (Page 209.)

Six miles of cables are required at Leyton; electrically driven pumps at Blackpool; steel tie bars and fish plates for tramway rails at Manchester; and stores at Islington. A loan of £600 for meters is to be asked for by the Southampton Council. Loans have been sanctioned at Stepney (£10,000) and Woolwich (£753). A battery is to be installed at the Dickinson Street works of the Manchester Corporation. (Page 210.)

At the annual meeting of the Westminster Electric Supply Co., complaint was made of the large sums which have to be paid in rates. The Chairman of Messrs. Mather & Platt states that they are now able to supply gas engines up to 2,000 h.p. capacity. At the meeting of Messrs. Crossley Bros., it was stated that there is at present very little demand for gas engines of 500 h.p. and upwards. The National Telephone Co. are in negotiation with the Postmaster-General with a view to arriving at a scheme for continuing to expend capital in advance of requirements during the remaining years of their licence. Mr. George Sutton, Managing Director of W. T. Henley's Telegraph Works Co., Ltd., is to be presented with his portrait and a service of plate to the value of £1,000. The Metropolitan Electric Supply Co. announce a dividend on the ordinary shares making 5½ per cent. for the year, and the Chelsea Co. 4½ per cent. on the ordinary shares. (Page 212.)

The specifications published by the Patent Office on Thursday included one by A. D. Jones for a form of globe for an enclosed flame arc lamp. Cooled metallic surfaces are provided in the upper portion to receive the deposit, while a rapid circulation of the fumes is induced, and the lower portion is kept hot to prevent clouding of the glass. A process for the manufacture of filaments consisting of a mixture of tungsten and zirconium oxide has been patented by the British Thomson-Houston Co. Other patents relate to compensated auto-transformers, clips for wiring-conduit, heating apparatus, and traction motor control. A. Swan, of the General Electric Co., U.S.A., has applied for the amendment of a patent for a lamp base in which the metal shell is interlocked with a glass button uniting the contacts, and Mavor & Coulson, Ltd., wish to amend a specification for a variable speed polyphase motor. Opposition has been entered to the grant of a patent to Siemens & Halske Akt. Ges. for a process of manufacturing metal filaments in which a ductile mixture of nickel and tungsten is first produced. The grant of a patent for vulcanising apparatus is also opposed. Short abstracts of the above specifications are given in our Patent Record. (Page 215.)

The Paper on "Flywheel Equalisers," by Mr. J. S. Peck, read last week before the Manchester Local Section of the Institution of Electrical Engineers, after referring to some continuous current systems and the alternating current system employing a rotary-converter and a continuous-current flywheel equaliser, as used in the winding plant of the Great Western colliery, described one or two modifications of a system employing single-phase commutator machines capable of acting either as motors or generators in conjunction with a flywheel. (Page 217.)

The discussion on Messrs. Andrews and Porter's Paper on "The Use of Large Gas Engines for Generating Electric Power," was resumed in London last Thursday. Mr. H. A. Humphrey, who upheld the authors' figures, compared the efficiency and overload capacity of a steam boiler with those of a gas producer, and also made some interesting statements with regard to some experiments he was making with a combined gas pump and water turbine, in which the water was put under pressure by gas explosions. Mr. Highfield said it would be a mistake for engineers to apply the gas engine at the present time on a large scale to power station use. Most of the difficulties experienced were, he thought, due to the fact that there were few men who understood the gas engine sufficiently. Mr. E. G. Schmer said that he could supply gas engines at a considerably lower cost than was assumed in the Paper, and that he could guarantee a much lower repair bill. The adoption of 1,000-h.p. units in preference to larger sizes was advocated by Mr. Dowson. Mr. A. M. Taylor put forward an alternative scheme for the gas plant, which included a battery for dealing with the peak loads. There were a few other speakers, and a written communication has been received from Mr. Mioskowski, of the Augsburg-Nurnberg Maschinenfabrik. (Page 219.)

Speaking at the annual dinner of the Manchester Section of the Institution of Electrical Engineers, Mr. Ferranti condemned the system of the lowest tender, the result of which he said was that there was no longer any such thing as "goodwill" in the electrical industry of this country. (Page 222.)

The flame arc lamp, on account of its high efficiency and pleasing appearance, is now the accepted means of exterior illumination. For the lighting of the fronts of theatres, restaurants, and other large public buildings, it is certainly unequalled; and it is already much in vogue for shop-window lighting, as well as for street lighting, in spite of the rather limited horizontal illumination which is obtained. In order to render the flame arc lamp more suitable for this latter purpose, certain makers have already put lamps on the market with vertical superposed carbons, and the difficulties in striking the arc, due to the ash and slag from the impregnated carbons, which were originally experienced, and were partly the cause of the adoption of the converging carbon arrangement, have been apparently overcome. An example of a vertical carbon flame arc lamp was described in Electrical Engineering for February 18th. With the same purpose, the makers of the "Excello" converging carbon lamp have developed the prismatic inner globe, which we described last week, and which throws a large proportion of the vertical rays from the arc in a horizontal direction. This inner globe has also the effect of preventing the deposit of the ash on the outer globe and the consequent absorption of the light from the arc. Good design and workmanship in the feeding mechanism, and the use of carefully prepared carbons, have prac-

Digitized by Google

tically eliminated the unpleasant flickering once associated with the flame arc lamp, but the latter still falls short of the pure carbon enclosed lamp in point of burning hours, except in the magazine type. By using long carbons, and, as exemplified by recent patterns of the "Excello" and "Eclipse" lamps, by employing two pairs of carbons which are burned in succession, the burning hours of the ordinary flame arc lamp can be extended to as much as 35 hours without unduly raising the cost of the lamp, but there is every reason to believe that before long the enclosed flame arc lamp will be a most serious competitor of the magazine lamp for the illumination of very large spaces. There is already an enclosed flame arc lamp on the market, and we notice that the inventor of this, Mr. A. D. Jones, is still working in this direction. In our Patent Record this week will be found a short abstract of a recent patent taken out by him for a form of enclosed globe intended for use with either convergently or vertically arranged flame carbons. The upper part of the globe is of metal, and is kept as cool as possible, so as to assist deposition on its surface, while the lower glass portion is kept hot by means of an outer glass globe and an insulating air space. A continuous circulation of the fumes and particles of ash is induced, and it is said that the globe is kept comparatively clear. Not only are the burning hours of the carbons increased owing to the slower combustion, by enclosing the arc, but the cost of carbons should be considerably reduced.

The advantages to be gained by the provision of means for equalising the load in cases where heavy peaks are of frequent occurrence—such as in electrical winding engines, rolling mills, and to some extent also in traction work—are generally agreed upon. In general, there are two principal methods available: the use of a battery or the storage of kinetic energy in a flywheel. Each method has its own field of usefulness, and the determining factor as to which is most suitable in a particular case is chiefly the shape of the load-curve. A battery can store a far larger total amount of energy than a practicable flywheel, but a flywheel can give up a much larger proportion of its stored energy in a much shorter time. In some classes of work, such as for non-reversing rolling mills, the flywheel may be attached to the motor itself and provision made for automatic speed regulation to enable the energy to be stored or given out as required. This can be effected without difficulty either with continuous or alternating currents. The case of the reversing mill or the winding engine is different; a flywheel is impossible on the driving motor-shaft, so a separate machine, electrically but not mechanically linked up to the system, must be provided for the flywheel itself. Several methods are in use. Either, as in the Ilgner system, the flywheel can be attached to a motor-generator converting the whole power from the form and pressure at which it is supplied into continuous current at varying pressures, or as in the Braun system used by the Westinghouse Co., a single machine may be coupled to the flywheel and employed alternately as motor or generator to smooth out the peaks, dealing only with the difference of the actual load from the normal. With an A.-C. supply both these systems, and some others not unlike them, involve a conversion into continuous current, as the flywheel set demands a continuous-current machine. In the Ilgner system the whole of the power is thus converted, and continuous-current main motors are employed; while in the Westinghouse system only that part of the power dealt with by the flywheel equaliser is passed through a rotary-converter. It was a solution of the problem of how to avoid this conversion that Mr. J. S. Peck put before the Institution of Electrical Engineers at Manchester last week. The scheme he has developed, which we hope to see soon in use, takes advantage of the properties of the single-phase commutator-motor by an interesting device for the provision of excitation at the correct phase angle for enabling it to run as a generator when required.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MARCH 4TH.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster. Paper to be read :—"Some Commercial Aspects of the Management of Central Electricity Supply Stations," by R. Borlase Matthews.

Röntgen Society.

8.15 p.m. Meeting at 20 Hanover Square, London, W. Paper to be read :—"Some Vacuum Tube Phenomena," by A. A. Campbell Swinton.

MONDAY, MARCH 8TH.

Royal Society of Arts.

8 p.m. Cantor Lecture IV. :—"Methods of Illumination," by L. Gaster.

TUESDAY, MARCH 9TH.

Institution of Electrical Engineers: Manchester Section.

7.30 p.m. Meeting at the University. Paper to be read :—"Electric Traction Vagabond Currents," by R. G. and J. G. Cunliffe.

[The meeting of the Glasgow Section of the Institution of Electrical Engineers has been postponed until Friday, March 19th, when a "Note on the Safety of Working Electrical Plant in Coal Mines" will be read by S. A. Simon.]

WEDNESDAY, MARCH 10TH.

Institution of Electrical Engineers: Birmingham Section.

7.30 p.m. Meeting at the University. Paper to be read :—"Extending the Limits of Power Transmission," by A. M. Taylor.

Association of Engineers-in-Charge.

8 p.m. Meeting at St. Bride's Institute, Bride Lane, Fleet Street, E.C. Paper to be read :—"Indicator Diagrams," by W. A. Tookey.

THURSDAY, MARCH 11TH.

Institution of Electrical Engineers.

8 p.m. Meeting at 25 Great George Street, Westminster. Paper to be read :—"The Dielectric Strengths of Compressed Air," by E. A. Watson.

Institution of Electrical Engineers: Dublin Section.

8 p.m. Meeting at the Royal College of Science.

FRIDAY, MARCH 12TH.

Physical Society.

8 p.m. Meeting at the Imperial College of Science, Imperial Institute Road, South Kensington. Agenda :—(1) A. E. Garrett, B.Sc., "The Effect of Radiations on the Brush Discharge." (2) E. C. Snow, B.A., "On Pirani's Method of Measuring the Self-inductance of a Coil." (3) W. S. Tucker, B.Sc., "Exhibition of a High-potential Primary Battery." (4) H. S. Rowell, "On the Least Moment of Inertia of an Angle-bar Section."

Royal Institution.

9 p.m. Evening Discourse on "Modern Submarine Telegraphy," by S. G. Brown.

Private Telephones.—In answer to a question in the House of Commons on Friday with regard to allowing private telephone installations to be connected up with the Post Office system, the Postmaster-General stated that the majority of internal telephone systems fitted in private premises were quite unsuitable for use in connection with the public exchange system, especially where trunk communication was desired. He could not, therefore, agree to the proposition, but there was no difficulty in arranging for the establishment of private branch exchanges giving all facilities for communication between the different parts of business establishments as well as with the public exchange system.

16-CANDLE-POWER OSRAM LAMPS

THE Deutsche Gasglühlicht Akt. Ges. (Auergesellschaft), the makers of the Osram lamp in Germany, have just placed a 16-candle-power, 100-130-volt lamp on the market in that country. It is stated that the lamp has a consumption of 18 watts, or 1·12 watts per Hefner candle (approximately 1·3 watts per British candle). It is supplied for parallel running at the price of 2s., and in small quantities for series running at an extra charge of 3d. per lamp. Supports for the filaments are provided at the ends of the loops, and the lamp burns in all positions. The normal lamp is pear-shaped, but spherical globes can be obtained at an enhanced cost. Particulars as to the dimensions of these lamps are not yet to hand.

In the first week in February, some of the Osram lamps previously put on the market were considerably reduced in price in Germany; thus, the 40 and 50 c.p. 200-250-volt lamps, which originally cost 5s. apiece, are now listed at 3s. 6d. A reduction in the price of the 100-c.p. 100-130-volt and 200-250-volt lamps to 4s. 6d. was also made.

The Wolfram Lampen Akt. Ges. of Augsburg have also put a 16-c.p. 100-130-volt tungsten lamp on the market. This lamp is also listed at 2s., an extra charge of 3½d. being made for spherical bulbs. Lamps for series running are listed at 3d. extra. The efficiency is stated to be about 1 watt per Hefner candle. It will be remembered that the lamps sold by the General Electric Co. of this country are manufactured under the patents owned by both the above company and the Auergesellschaft.

In response to our inquiries, the General Electric Co., Ltd., inform us that they are as yet unable to say when the 16-c.p. Osram lamp will be on the British market, as it is not yet possible to obtain commercial deliveries in this country.

Contemporary with the reduction of the price of Osram lamps, the price of the 40-50-c.p. 200-250-volt metal filament lamp manufactured by the Bergmann-Elektricitäts Werke has also been reduced to 3s. 6d. The Phillips' Metall Glühlampen-Fabrik. A.G. of Eindhoven, Holland, have also reduced the prices of their 50-c.p. and 100-c.p. lamps, so as to correspond to the Osram figures, namely, 3s. 6d. and 4s. 6d. respectively. Another firm which has reduced its prices in Germany is the Allgemeine Elektricitäts Ges.; this firm's 25-50-c.p., 100-130-volt lamps are listed at 3s., and the 50-c.p. 200-250-volt lamps at 3s. 6d. An enterprising German firm, the Zirkon-Glühlampenwerk Dr. Hollefreund & Co., are advertising a new lamp, the "doppel Z-Lamp," with an efficiency of 0·7 watt per Hefner candle. A saving of 30 per cent. in comparison with Osram and other metal filament lamps, and 80 per cent. in comparison with carbon filament lamps is claimed, but the effect on the life of the filament of running at this high efficiency is not stated.

THE ELECTRICAL INDUSTRY AND TARIFF REFORM

THE annual staff dinner of the General Electrical Co., Ltd., was held last Saturday, and, as usual, a number of prominent men in the electrical engineering industry had accepted the company's invitation to be present.

Mr. Gustav Byng, Chairman of the company, who presided, proposed the toast of "Electrical Science and Industry." He spoke first of the early days, twenty years ago. "In those days," he said, "we manufactured, and our professors used to tell us how we did it. . . . Large quantities of electrical goods manufactured in England in those days were sent abroad to all parts of the world. We sent to America, to Germany, and to France, dynamos and lamps, cables and wires, and especially measuring instruments and meters. We also exported a large number of telephones. Some of you may hardly believe it, but that is a fact. [A Voice: Only parts.] No, not only parts. Telephones, real live telephones that would speak. I remember well that then England was first and Americans and Germans and Frenchmen used to come to London to buy electrical goods and learn. One of the main things we used to send abroad were electrical books, text-books, and we taught the foreign people. It seems strange to-day, but it is nevertheless true, that twenty years ago in matters electrical England led the world. And no wonder. If we go a few years back, we find that every invention, every discovery upon which electrical science is based, was a British invention or a British discovery. We are apt nowadays to forget that. And to-day, are we still leading? Our British electrical industries are still vast and important and virile, but, alas! there are too many signs, to my mind, that we have lost our lead, and that to-day we have to follow in matters electrical. On many vital points there is no difference. We still have our scientists, our inventors, our employers, and our workmen the same as we had them twenty years ago. We have the demand, we have the money, we have our factories, and our machinery; our climate, our spirit, our enterprise, and courage, all I hope are the same. I have come to the conclusion that the difference lies in the methods by which foreign Governments support their industries, and those by which we here in England are supported by our Government. I see the foreign manufacturer of electrical machinery flourishing under a protectionist tariff, whilst our industry began to languish ever since we felt the influence of free imports." Continuing, Mr. Byng said that he would put down a prize of twenty guineas for an essay which proved that the state of affairs is due to any other cause than the fiscal position under which we work. He would be quite content to leave the decision to an advocate of free trade, say Mr. Swinburne, Colonel Crompton, or even the Editor of the *Electrical Review*. He had prophesied in his book, published in 1901, that Free Trade would come to an end by 1912, and he looks forward to the fulfilment of that prophecy. All we ask, Mr. Byng concluded, is that English electrical manufacturers may be able to work under the same conditions as electrical manufacturers abroad. Then their order books would be full, their factories busy, and increases of salary would not be refused.

Mr. Byng's speech was punctuated with enthusiastic applause and cheers, and it was evident that the majority both of his own staff and of the guests were in agreement with him as to the ultimate benefit likely to accrue to the electrical industry by a revision of our fiscal system and the imposition of a protective tax on foreign manufactured imports.

Mr. W. M. Mordey and Dr. R. T. Glazebrook, who replied, both avoided the political aspect of the question; Mr. Mordey is known to be a Free Trader, and Dr. Glazebrook, in his position of Director of the National Physical Laboratory, could, of course, not express his political opinions. [By the way, we overheard Dr. Glazebrook's institution referred to as the National Fiscal Laboratory—but that was later on in the evening.] Mr. Mordey said that in spite of the bad times alluded to by Mr. Byng, the General Electric Co. employed between five and six thousand workmen, and that Mr. Byng had been able to establish his great business by making use of material imported from abroad free of duty. He then quoted his now familiar figures to prove that the British electrical industry was still leading the world. Dr. Glazebrook explained that foreigners had realised sooner than we had done the value of science to the electrical industry, and expressed the pious hope that the bond will grow closer.

Mr. Robert Hammond, in proposing "Imperial Trade," was ready with statistics to justify his free trade principles, and said that British goods received preferential treatment in many countries. The Hon. Cornthwaite H. Rason (Agent-General for Western Australia) and Mr. Edwin Grant Burls, C.S.I. (Director-General of Stores, India Office) responded, and it was pointed out that the preferential treatment referred to by Mr. Hammond was only accorded by our own colonies and dependencies. In the course of his speech Mr. Burls mentioned the fact that the Mint in Calcutta, which, he said, is the largest Mint in the world, is equipped with electric power, with the General Electric Co.'s plant. Mr. F. H. Medhurst, who proposed "The Electrical Press," said that there was, at any rate, no doubt that our technical Press was second to none. Prof. Silvanus P. Thompson gave the toast of "The General Electric Co.," to which Mr. Hugo Hirst, the managing director, responded. Mr. Hirst, who was received with prolonged cheers, testified to the whole-hearted assistance given by all the members of the staff in promoting the welfare of the company.

Institution of Electrical Engineers.—The following is the result of the ballot of new members at the meeting on Thursday:—*Associate Members:* J. H. Adamson, H. Aldum, W. K. Dickson, A. Dover, G. J. Macdonald, J. E. MacEwan, A. Page, C. T. Peacock, J. W. O. Sandell, E. E. Sharp, J. Shaw. *Associate:* A. D. C. Parsons. *Students:* A. C. E. Anthony, R. T. Challoner, W. G. Covell, N. B. Deane, W. A. Douglas, C. R. Ford, F. T. Gerstenberg, A T. Gilbride, P. Grice, W. J. Hannah, L. V. Hart, A. Henderson, E. R. Hillman, D. Jackson, S. Johnson, J. H. Jones, W. P. Kemp, E. W. Knott, B. W. Leak, D. H. Linsley, H. J. Loughlin, W. Mark, F. P. Matthews, A. G. Mitchell, F. Oglesby, W. Parry, L. S. Payne, S. H. Pook, H. Roberts, G. Sharples, W. Sherley-Price, A. Smellie, G. C. Smith, Wei-Shan Tcha, R. Thomson, E. F. Turner, T. H. Varcoe.

THE ELECTRICAL EQUIPMENT OF LINERS AND BATTLESHIPS

MR. A. P. CHALKLEY read a Paper on the above subject at an informal meeting of the Newcastle Local Section of the Institution of Electrical Engineers. He remarked that on board ship there was probably not a single case where the supply voltage was above 120, mainly on account of the following objections:—(1) The difficulty of maintaining good insulation in any cables or switches exposed to the action of sea air, leakage being especially liable to occur in plugs and switches on the upper decks, and this increases rapidly with a higher voltage. (2) Many of the minor appliances in warships cannot be satisfactorily worked above 110 volts. (3) Lamps above 110 volts have delicate filaments, and do not last so well as those of lower voltage, and renewals in the ordinary way constitute a very serious item. (4) There is more danger of fire and risk to person, especially as at sea so few precautions are taken by those responsible for the electrical plant and men totally unused to, and ignorant of, electrical gear are frequently set to operate it. It was probable, however, that a 2×110 volt three-wire system would soon be adopted in the British Navy, and, indeed, one large battleship was already wired in this way.

The generating plant on a ship is usually divided into smaller units than for a similar land installation, chiefly in order that the dislocation of one set shall not be so serious, and also because, in port, not more than one-fifth of the full output is required. Hence it is common to find at least four generating sets, while in some German boats seven have been installed. The author strongly urged the advantages of turbine rather than reciprocating sets, especially for units above about 500 h.p.

Coming to the question of distributing circuits, it was pointed out that a ship offers excellent opportunities for economically safeguarding against breakdown, since if we take a longitudinal section through the middle from the bows to the stern the electrical loads on the two sides can be made practically equal. Hence by having several sub-switchboards or section boxes at similar points port and starboard, and joining them by heavy cable (the distances, of course, being very small) a duplicate wiring is obtained with practically no increase in cable outlay, one-half of the cables coming from the main switchboard to the port sub-switchboards, and the other half to the starboard sub-switchboards.

The further precaution is sometimes taken of having two separate switchboards in separate compartments, each taking one-half the entire load; usually they are joined by a heavy connecting switch, and so form virtually one board, but in case of emergency this switch may be opened from either board, leaving two separate installations, and, if necessary, one board may supply the whole ship.

The arrangement of some typical switchboards was discussed. The lighting and power feeders are sometimes kept separate, and sometimes combined, and, especially in large ships, the power circuits are protected by time limit circuit breakers instead of fuses. As a rule, switchboards are boards only in name, and though passenger boats often possess elaborate slate panels on which the switches, &c., are mounted, nearly all battleships have everything fixed direct to angle bars, which really constitute the board. It makes a sound if inartistic piece of work. the switches being bolted to the bars, from which they are well insulated by mica, or micanite, so that no shock, however severe, would dislocate any portion of the equipment. With a slate base, heavy firing, accompanied by severe vibration, might cause the slate to smash and damage some of the circuits.

The applications of electric power to heating ventilation, &c., was referred to, and the use of fans to supply air at the desired temperature from thermo-tanks was explained. The advantages of electrically-driven forced draught fans were also pointed out, but the necessity of placing them above the boilers out of reach of coal dust was emphasised. Various other uses to which electric power may be advantageously put on board ship were also referred to, including hoists, lifts, winches, cranes, refrigerating plant operation of large sluice valves, and engine dismantling, a purpose for which, particularly on warships, electricity is fast replacing hydraulic power.

It is impossible, continued the author, to mention all the minor applications of electricity on ships; for domestic and cooking purposes practically no other means are employed; telephones are largely used—the *Mauretania* has an installation of 80—a wireless telegraphy is a necessity. Electrically operated steering gear has been tried in one or two instances, but air, circulating, and auxiliary pumps have not yet received attention, probably on account of their size. It may be anticipated, however, that all auxiliaries will finally be electrically driven, the main and generating engines being the only steam plant, when the maximum attainable efficiency and convenience in ship's machinery will be reached.

In conclusion, the author said a few words on the proposed use of electric transmission gear to enable better efficiency to be attained by higher turbine speeds and lower propeller speeds. The opinion was expressed that while there might be doubts as to the superior economy of the system for large high-speed boats, it might compare favourably with the simple turbine system for smaller and slower ships, where the weight and steam consumption are relatively higher. While, on the one hand, we have the supplementary cost and weight of dynamos and motors, this is to some extent balanced by the smaller boiler equipment (due to lessened steam consumption), and auxiliaries, and the absence of astern turbines and propeller shafts. The question, commercially considered, hinges on the relative saving in coal consumption and loss on first outlay, and it seems probable that ships of moderate size, of from 14 to 18 knots, might with advantage use electric propulsion, though perhaps the system would not be more economical than the combination of reciprocating engines and low-pressure turbines.

At the end of the Paper some slides were shown illustrating proposed arrangements for electro-mechanical propulsion, and an arrangement was shown of a tug for ferry work. The tug itself was a power station, cables connecting it to the ferries, which were fitted with propellers driven by electric motors. In a proposed arrangement for a cargo boat, the main engines were coupled directly to propeller shaft, and the exhaust passed into a turbine coupled to a generator which drove a motor on the main propeller shaft, thus helping the main engines. In another proposed arrangement, the main engines were coupled to a propeller through a clutch for fast cruising, but the drive for running slow or reversing was through a generator and motor..

DISCUSSION.

In the discussion Mr. A. L. E. DRUMMOND (North-Eastern Railway), in the chair, hoped that telephones would be more used in future on board ship.

Mr. BAXTER, speaking for Mr. CLOTHIER (Messrs. A. Reyrolle & Co.), advocated simplicity of apparatus in the switchgear, especially the adoption of single bus-bars as used in large land plants.

Mr. RALPH (Messrs. J. H. Holmes & Co.) stated that the Admiralty practice in the battleships of *Dreadnought* type and in the *Invincible*, was 220 volts, but not on the three-wire system; 200 volts was also now used in some of the cruisers.

Mr. W. P. DURTNALL favoured a polyphase system of supply, using three-phase with 240 volts for motors and 100 volts for lighting. For ventilation and forced draught he advocated induction motors, varying the speed by "floating-field" generators. He stated that a boat was being built by the German Government fitted with turbines driving generators, and supplying power to motors on propeller shaft. In marine work 30 per cent. more steam per h.p. was used than in land practice, which he attributed to the slow speed of the marine turbine. The *Lusitania* used 12·77 lbs. steam per b.h.p. hour, while on land 11·1 lbs. of steam per kilowatt, or 8·8 lbs. per b.h.p. hour, had been attained. He had also seen designs of a cargo boat to be fitted with gas engines, using suction gas, and also another boat of 1,000 tons, to be fitted with two Diesel oil engines of 100 h.p. each, the engines to run at 300 r.p.m. and the propeller at 40 revs. The published results of *Dreadnought's* steam consumption was 14 lbs. per shaft h.p. He calculated that a saving of 26 per cent. would have been effected if electric drive had been adopted.

Mr. G. G. STONEY (Messrs. C. A. Parsons & Co.) attributed the less good steam consumptions obtained with marine turbines to the fact that at sea no superheat was used, and the vacuum was comparatively poor. He was not inclined to credit Mr. Durtnall's figure of 11·1 lbs.

Mr. DEAN stated that the consumption on the *Lusitania* was very good at 12·71 lbs. per h.p., as plenty of turbines on land used 13·8 lbs. per h.p., even with slight superheat. Superheat was not used at sea, owing to salt and oil causing corrosion. But with turbines there would be no oil and much less salt make-up water required, so that superheat ought to be tried again. He thought that with the increased efficiency of the propeller and efficiency of turbine with superheat, that 25 per cent. economy would be attained.

Mr. A. H. Law (Messrs. C. A. Parsons & Co.) thought that superheat would benefit the direct-drive turbine plant as much as the electro-mechanical equipment.

Mr. Chalkley replied briefly.

LONDON COUNTY COUNCIL TRAMWAY ACCOUNTS

MR. T. BARCLAY COCKERTON, the London County Council District Auditor, has presented his report upon the accounts of the Council for the year 1907-8. Dealing with the tramways undertaking, he states that the total capital expenditure during the year amounted to £1,468,280, about half of which was in respect of the construction of permanent way and erection of car-sheds.

The total receipts during the year from lines worked by electric traction amounted to £1,274,660, and from lines worked by horses to £388,371, equal to 11·95d. and 9·35d., respectively, per car-mile run. The total expenditure on lines worked by electric traction amounted to £724,381, and on lines worked by horses to £445,754, equal to 6·79d. and 10·73d., respectively, per car-mile.

The sum of £550,279, representing the surplus from lines worked by electric traction, was carried to the credit of net revenue account, and the sum of £57,563, representing the loss on lines worked by horses, was debited to net revenue account. After all proper charges have been debited to the net revenue account, a surplus is shown of £45,406. The balance to the credit of the appropriation account at the beginning of the year amounted to £5,923, to which sum has been added the surplus from net revenue account (£45,406), making a total sum to the credit of the appropriation account at March 31st, 1908, of £51,329, the whole of which has been transferred to renewals fund. The expenditure on renewals charged against this fund during the year under audit amounted to £3,992. The balance on this fund at March 31st, 1908, was £158,622. The Council, by a resolution passed on June 23rd, 1908, agreed that provision should be made for renewals in respect of the Council's electric tramways at the rate of two-thirds of a penny per car-mile run. Calculated on this basis, the amount standing to the credit of this fund on March 31st, 1908, should be £196,741. At this date, however, the amount remaining in the fund fell short of the last-mentioned sum by £38,119.

A general reserve fund has been established during the year for the purpose of providing for "general contingencies," and has been credited with an amount of £34,634, transferred from renewals fund. No charge has been made against the general reserve fund during the year under audit.

The above-mentioned reserve funds are not charged with the annual expenditure on "repairs." The annual expenditure on repairs is debited against revenue account as part of the working expenses of the year. During the year under audit no less than £140,670 was charged to revenue for repairs on electric traction.

The auditor continues as follows: In establishing these reserve funds it would appear that, strictly speaking, the Council are making provision over and above that required by statute. At the same time it should be borne in mind that the Treasury have sanctioned certain fixed periods within which capital expenditure on tramways should be repaid, on the distinct understanding that all renewals should be defrayed out of revenue. The conditions laid down by the Treasury as to the repayment of capital show that funds such as those referred to are practically, if not absolutely, necessary. Moreover, there is, at the present time, a want of experience and knowledge with regard to electric traction as to whether the life of the asset will be as long as the loan period. This in my opinion affords a very strong argument in favour of maintaining reserve funds such as those established by the Council, and, further than this, the creation of these funds will equalise the annual charge to revenue for renewals. If these funds did not exist, it is quite clear that the whole expenditure for renewals in one particular year would fall upon the revenue of that year. As far as the accounts show, the tramways belonging to the Council appear to be worked on a very sound financial basis, and all contingencies which are likely to arise seem to be adequately provided for.

Electric Shock on Tramcar.—In the King's Bench Division of the High Court on Monday, an action by a man named Clark against the West Ham Corporation, for damages from shock through coming into contact with the trolley post on the top of one of the Corporation's tramcars, was commenced. It appears that on July 20th, 1907, the plaintiff, who was at the time a tram driver in the employment of the Corporation, was travelling on the upper deck of a car as an ordinary passenger, and in order to steady himself placed his hand upon the trolley post, and received a shock which burnt his hands. He was for five months in the doctor's hands, and as a result of the weakness which followed he was discharged from the Army Reserve in November, 1907, and had lost £47 reserve pay in addition to 84 weeks' pay at 35s. per week from the defendants as a tramcar driver. The Corporation relied upon the statement in their book of rules, that passengers' compensation for injury was limited to £25, as they were being carried below the maximum fares authorised. On Tuesday the jury awarded £500 damages, but judgment was reserved pending consideration of some points of law.

VACUUM CLEANING FOR BOILER FLUES AND ECONOMISERS

A SPECIAL application of the vacuum-cleaning process has been developed (under Booth's patents) by the Vacuum Cleaner Company for the removal of dirt in flues, &c., of large batteries of boilers. The equipment required for the purpose includes a special pattern of two-cylinder vacuum pump, which can be driven off existing shafting or otherwise, and runs at 180 r.p.m. This pump can be placed any distance up to about 1,000 ft. from the boiler. Near to the pump are placed a pair of vertical vessels acting as dust filters connected to the piping leading from the boilers. These filters are usually placed outside the building under a roof, and sufficiently high to allow a cart to stand underneath for the reception of the dirt, of which each filter when full holds about a cartload.

The gun-metal cleaning nozzles are attached to flexible hose-pipes connected to special fittings near the boilers and economisers, and 1½-in. piping is used throughout. The standard size of equipment is capable of dealing with one ton of dust per hour, and with the two filter vessels no interruption is required for removal of the contents, as one can be filled while the other is being emptied.

The system has been in use for two years at a large works in Bradford, and it is stated that one of the sections of the economiser containing 400 pipes can be cleaned out by two men in three hours, during which period about four cartloads of dust are usually removed. Previous to the installation of this equipment, the cleaning of the economiser took three men about ten hours. Two men can clean out one of the boiler flues at the same works in three hours, while formerly three men were required working ten hours.

The Bournemouth Tramways Arbitration.—Probably the last has now been heard of the arbitration proceedings under which the Bournemouth Corporation acquired the undertaking of the Poole & District Electric Traction Co. The arbitration commenced as far back as 1904, but various matters in dispute have been before the Courts at different times, and these culminated in a decision of the House of Lords on Monday which finally disposes of the matter. When the Corporation took over the undertaking two sums remained in dispute, viz., a sum of £6,476 bank overdraft, and sums due to creditors, and £2,750 Parliamentary deposit, &c., all of which were claimed by the company to be part of the undertaking in respect of which they should be indemnified. In the first instance, the Court decided in favour of the Corporation, but the Appeal Court reversed this decision, which the House of Lords now upholds, these liabilities having been incurred by the company in the ordinary course of business.

Telegraph Traffic.—The lines of the Indo-European Telegraph Company were interrupted on the 24th ult. between Rowno and Odessa, and on the same day the submarine telegraph cable between Malta and Zante owned by the Eastern Telegraph Company ceased working. On Feb. 26th the cable between Seattle and Sitka was again in order. The people of Montserrat, one of the West Indian islands, desire to have telegraphic communication with Antigua, a neighbouring island, and are preparing a petition to the Governor.

Wireless Telegraphy and Telephony.—The West India and Panama Telegraph Company are making progress in the installation of the Lodge-Muirhead wireless stations at Trinidad and Demerara. The area occupied by the station and aerials in Demerara is 5 acres, and is situated 300 yards inland. The building is 45 ft. long, has a double roof, and is teak-lined. A 7 h.p. oil engine drives the alternating-current generator. Nine masts of Oregon pine have been erected. The main mast is 235 ft. high; four are 26 ft. high, and are to be placed inside of the square enclosing the main mast; while the remaining four masts, each 82 ft. high, will be put up outside. It is expected to have the installation in working order in a few weeks. Work at Trinidad has also advanced considerably.

The wireless station on the Eiffel Tower has been receiving messages from Glace Bay, Canada, a distance of 3,250 miles. With the new installation which is being put in (see ELECTRICAL ENGINEERING, Vol. IV., page 843), it is hoped to establish communication with Saigon, a distance of 6,800 miles.

On Saturday some successful experiments were made in America to test the practicability of using wireless telegraphy on an express train running between New York and Chicago.

Wireless apparatus is to be installed on all the Great Eastern Railway steamers of the Harwich-Antwerp service.

The New York correspondent of the *Standard* states that Government regulation of wireless telegraphy will probably be introduced shortly, as the large number of private stations are a source of considerable trouble to the commercial and naval stations. It is said that there are fifty installations in the borough of Brooklyn alone; one troublesome individual has erected a station with a range of 200 miles.

An order has been issued that no person shall establish any wireless telegraph installation in the Somaliland Protectorate without a licence from the Commissioner.

HIGH-TENSION SWITCHBOARDS WITH REMOVABLE SWITCH CARRIAGES

AN interesting system of high-tension switchgear has been developed during recent years by the Felten Guilleaume-Lahmeyerwerke Co., of Frankfurt, in which the important requirements of inaccessibility of live parts during work and ease of access together with safety for cleaning, &c., have been effectively combined by following the usual cellular construction, but placing the high-tension switchgear contained in each cell upon a framework mounted on wheels, which may be withdrawn from the switchboard on a truck provided for the purpose. Connection is made to the 'bus-bars and other circuits by plug contacts, which only engage when the carriage is pushed into its working position. A further advantage of the system is that a spare switch carriage may be provided, so that in the event of extensive adjustments or repairs to the high-tension gear becoming necessary, the part concerned may be replaced, and the machine or feeder connected to it will not be put out of operation for any serious length of time.

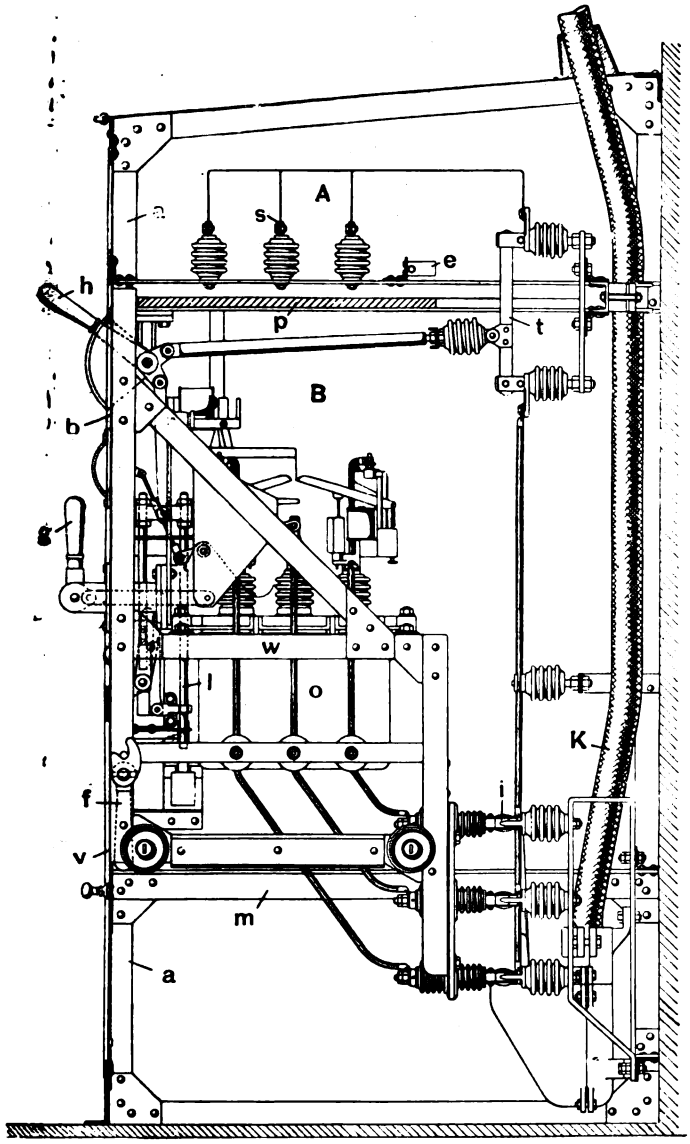

FIG. 1.—SECTION OF SWITCHBOARD SHOWING CARRIAGE IN PLACE.

The front wall of the switch carriage is generally completely closed, and is equipped with switch handles and measuring and controlling instruments, so that the carriages form a complete switchboard panel when in position.

An interesting example of this system, as applied to an underground mining switchboard, is seen in Fig. 1, which shows a section of a complete three-phase switchboard as described above. Each cell consists of an angle-iron framework completely covered with sheet-iron, which can be mounted directly up against the wall, and is divided into two chambers by means of a horizontal insulating partition p. The top chamber A contains the high-tension 'bus-bars s mounted on porcelain insulators, and the lower one B the actual switchgear. In addition to this, the lower chamber B of each cell is separated from the adjacent ones by means of vertical flame-proof partitions. The jaws of the three-pole isolating switch t, mounted in the 'bus-bar chamber A, are in direct connection with the 'bus-bars, and their

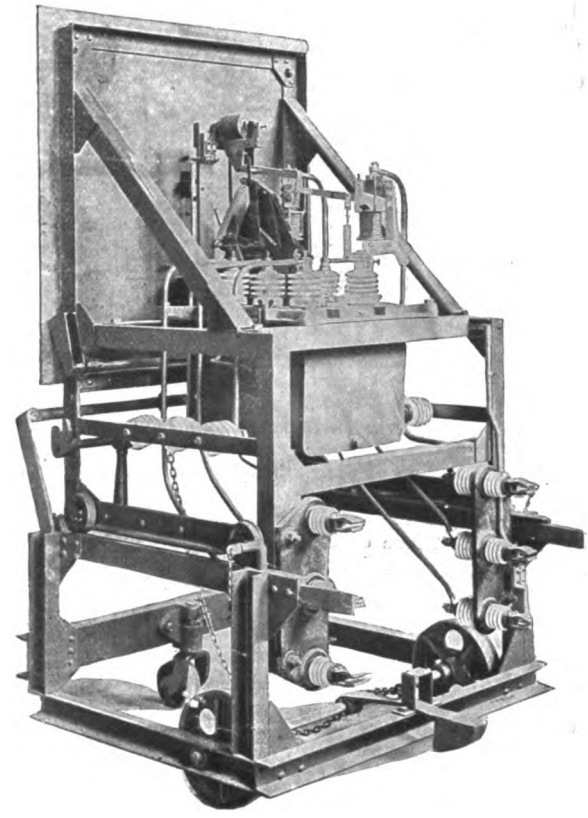

FIG. 2.—REMOVABLE SWITCH CARRIAGE ON TRUCK.

blades, which pass through suitable slots in the insulating partition p, are provided with earthing contacts e at their lower end. When one of the isolating switches is opened, all the apparatus carrying current, which are contained in chamber B, are completely isolated from the 'bus-bars, and all parts of the switchgear below the partition are in direct connection with the earth. The isolating switch t is actuated through a system of rods connected to the lever h, which is fitted to the rigid part of the switchboard front. The front of the top chamber A, as well as the front of the top part of the chamber B, is formed

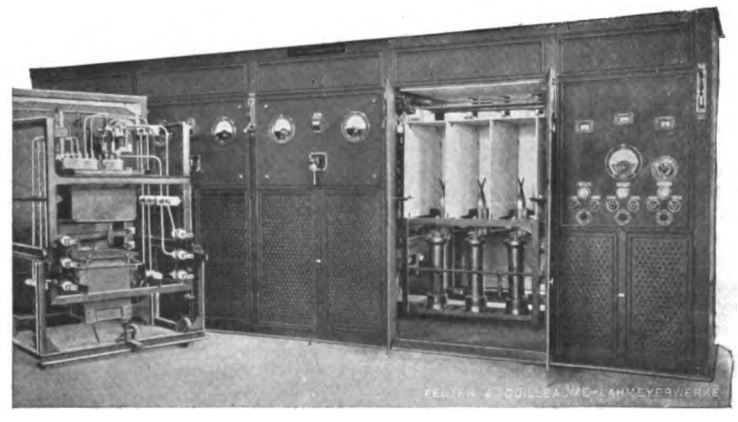

FIG. 3.—HIGH-TENSION SWITCHBOARD SHOWING CELL CONTAINING ARRESTERS WITH RESISTANCES.

Digitized by Google

by a rigid covering of sheet-iron, whilst sheet-iron folding-doors are fitted below that portion of the panel forming the front of the removable switch carriage.

The removable switch carriage *w* consists of a riveted angle-iron framework mounted on wheels, which runs on the rails *m*. It carries the oil-break circuit switch *o*, together with the relays and other auxiliary apparatus, the hand lever *g* for operating the oil switch, and on the sheet-iron front, mentioned above, the measuring instruments and signal apparatus. The connection of

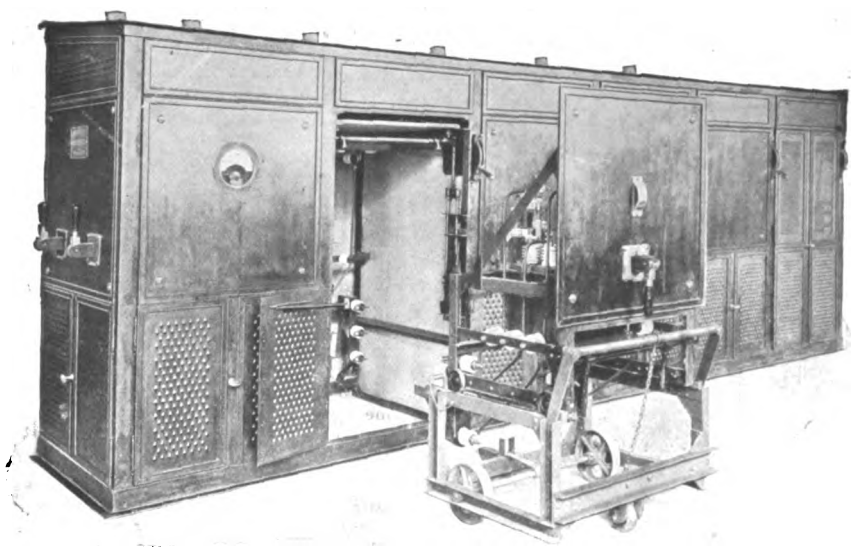

Fig. 4.—High-tension Switchboard showing Switch Carriage Removed.

this removable portion of the panel to the isolating switch *t* and the bus-bars *s* on the one side, and to the feeders *K* on the other side, is made by means of two sets of three-pole high-tension plug contacts *i*. These contacts are carried on the lower part of the switch carriage, into which fit the corresponding fixed contacts mounted at the back of the board. These fixed contacts are further fitted in such a manner that, after opening the doors at the front of the switchboard, they are easily accessible to the attendant. This is an important point, as it is of great advantage that the contacts may be examined when the switch carriage is in position, to obviate the possibility of their becoming displaced and to ensure their making good contact. The switch carriage is withdrawn from the switchboard by means of a truck provided for the purpose. After the folding doors *v* have been opened, this truck is wheeled right up in front of the switch carriage, to which it is fastened by means of a catch. The switch carriage may then be withdrawn from the switchboard for the purpose of testing or adjusting, and can, after loosening the catch holding same, be completely removed from the switchboard. In order to prevent jolting as much as possible whilst removing and replacing the plug contacts, the necessary horizontal motion of the switch carriage is effected by the claw-shaped handle *f* by means of an arrangement of levers, while the other motion takes place directly. The designers have further, by interlocking all the gear, provided a system in which all the necessary operations can only take place in a definite order. The lever *h* of the isolating switch is, in its "on" position, interlocked with the lower inspection doors *v* by means of the vertical rods *l* and with the switch carriage in such a manner that the former cannot be opened nor the switch carriage withdrawn as long as the plug contacts and the main switch are under pressure. In like manner the isolating switch cannot be closed while the doors *v* are open or the switch carriage is withdrawn. The isolating switch is further interlocked with the handle *g* of the main oil switch, so that the former can be opened or closed only when the latter is open, and there is thus no possibility of the isolating switch being opened while carrying current. In this way the opening of the doors *v*, and therefore access to the interior of the switch carriage and the withdrawal of same, can only be effected after the main oil switch and then the three-pole isolating switch have been opened, and by this means the whole switch carriage earthed and made dead. On the other hand, the isolating switch can only then be closed again and the switch carriage put under pressure after it has been replaced and both parts of the folding doors *v* closed.

Figs. 2, 3, and 4 show a 5,000-volt switchboard of the type described which is installed underground in the Franziska pit, Gelsenkirchen, Westphalia. The switch carriage is also specially adapted for receiving other apparatus, such as arresters, together with resistances and similar apparatus, as, for example, in the installation shown in Fig. 3. This form of construction is also suitable for building up central station switchboards, although with these the main advantages of the system, namely, the small floor space necessary and complete operation from the front of the board, are not of such consequence as with distributing boards in mines and other places.

For an installation of this description a space of maximum 8 ft., of which 4¼ ft. fall to the passage-way in front of the switchboard, suffices completely, as the depth of a normal switch-carriage frame intended for a pressure of 5,000 volts is approximately 4ft., and that of the carriage itself about 3¼ ft. Switchboards of the type for voltages up to 10,000 volts have been manufactured in considerable numbers.

"MIDLAND" TELEPHONE EXCHANGE, BIRMINGHAM

By H. S. Plymen

"Midland" Exchange, Birmingham, a new central battery exchange of the National Telephone Company's system, was opened last November with about 1,400 subscribers. These subscribers were previously working on "Central" exchange, which contains both magneto and central battery equipments. The majority were working on the magneto sections of the "Central," but a portion of the C.B. equipment had been reserved for "Midland" subscribers until the completion of the new exchange, to which they were then transferred without change of number.

The exchange is situated in Hill Street, a short distance from New Street railway station, and the site has a frontage of 100 ft. and a depth of 145 ft. The building at present erected has a depth of 94 ft., but it has been so constructed that it can be extended the full depth of the site when this becomes necessary. It is of fireproof construction throughout, and consists of five floors; the ground and first floors are occupied by the stores and offices; the second, by the apparatus, power, and accumulator rooms and the offices of the electrician's staff; the third, by the operators' apartments and school for instructing operators; and the fourth by the switchroom and offices of the traffic manager's staff.

A subway has been constructed under the building for the purpose of bringing in underground cables. Thirty vitrified earthenware conduits enter horizontally from each end, one-half of which are shown in Fig. 1. From the subway five groups of eight and one of three vertical conduits pass up into the apparatus-room and terminate in the cable-trench at the rear of the main frame. These conduits are built into the walls of the intermediate floors. The underground dry-core lead-covered cables, varying in size from 200 to 800 pairs, pass from the horizontal to the vertical conduits without jointing, and are led into the cable-trench, in which they are jointed to silk and cotton lead-covered cables with a solid joint. The latter cables pass through iron conduits in the floor to the rear of the fanning strips on the vertical side of the main frame, and are there laced out and soldered to the line fuses. The motor-compressor and desiccator are installed in the subway, and may be seen on the left in Fig. 1. From the desiccator a galvanised-iron pipe is run along the ceiling. To this the cables are connected when necessary by a short length of rubber tubing; one cable so connected may be seen in the figure.

The arrangement of the apparatus and accumulator rooms is shown in Fig. 4. The main frame has capacity for 15,000 pairs of wires, and is equipped for 6,750; each vertical arrester mounting accommodates 250 pairs. The frame can be extended in a straight line to accommodate the ultimate number of wires required for a 10,000-line exchange.

The intermediate distributing frame, relay, register, and special apparatus racks are of the standard design, the former

Digitized by Google

having capacity for 15,600 lines on the horizontal side. One repeating-coil rack and fuse-board is fitted for the repeating coils and fuses in both the A and B cord circuits, and a separate fuse-board is provided for the 30-volt supply to the registers and the private branch exchange power leads. This fuse-board

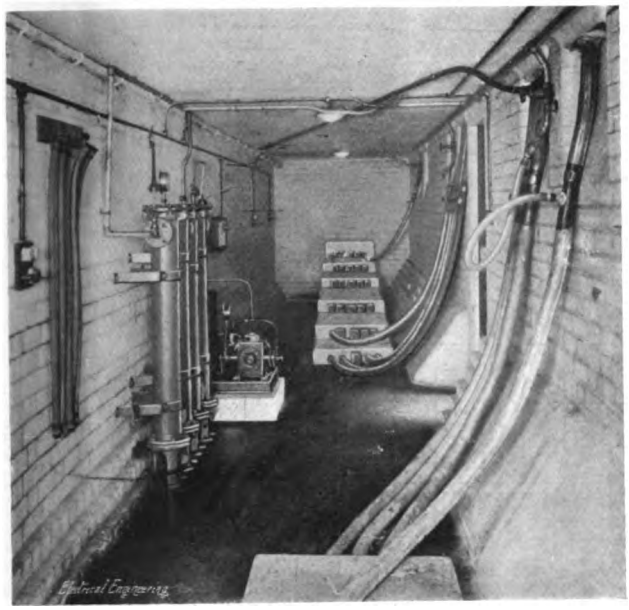

Fig. 1.—Cables entering Subway.

also carries the ringing and tone-test fuses and the resistance lamps in the ringing leads to private branch exchanges.

Subscribers' registers are provided for 1,300 subscribers on the measured-rate service. These are cabled with 105-wire cable to the intermediate distributing frame, where they are cross-connected to the subscribers' lines as required. The operators' registers are mounted on one bay of the subscribers' register rack instead of in a cabinet in the switch-room, as was formerly the practice.

The main battery of eleven cells has a capacity of 1,530 ampere-hours at a 9-hour discharge rate. The lead containing-tanks will accommodate plates having an output of 4,080 ampere-hours, and the portion of each tank not at present required is filled with a lead tank weighted with bricks. The capacities are designed to serve the present equipment for 1½ days, and a 10,000-line exchange for one day when the whole of the plates are installed. The battery of four cells, which is connected in series with the main battery for operating the registers and supplying the private branch exchanges, has a capacity of 420 ampere-hours at a 9-hour discharge rate. Two motor-generators for charging the cells and two ringing machines are installed. The charging generators have an output of 400 amperes at from 22 to 30 volts; each is direct-coupled to a 19½ h.p. motor run from the 440-volt direct-current mains. The ringing machines have an output of 2 amperes at 75 volts; one is direct-coupled to a 440-volt motor, the other is of the dynamotor type run from the 11-cell battery. Both ringing machines are fitted with interrupters to provide current for machine ringing on the B-positions and tone-test circuits.

The test-clerk's desk has two positions, and is of the multiple type.

The present switch-room has capacity for 56 A-positions and 27 B-positions, which will accommodate 7,000 lines with the necessary junctions. When the switch-room is extended there will be sufficient space for 91 A-positions and 42 B-positions, which will be necessary to provide for the number of lines which it is estimated will be working in the area served by this exchange by the year 1923. The A-sections turn through an angle of 180°, with 7 angles each of 25° 43′. The B-sections are in a straight line.

The equipment installed at present is for 2,740 subscribers' lines and 378 incoming junctions. These are accommodated on 34 A-positions, each equipped for 80 subscribers' lines, and 17 pairs of connecting cords, one testing operator's position, and 14 B-positions each with 27 incoming junctions. The switch-boards are made up of 8-panel 3-position sections of fire-protected construction, similar to those supplied for "Gerrard" Exchange, London, and described in Electrical Engineering of October 31st, 1907.

The subscribers' multiple is for 3,300 lines, multipled every 9 panels on the A-sections and 6 panels on the B-sections. This number provides for two jacks for each party line, in addition to the necessary spares for changed numbers.

The outgoing junction multiple is for 380 junctions on the A-sections and 120 on the B-sections. In each case the jacks are in strips of twenty, and are multipled every 6 panels.

All circuits are on the Western Electric Company's standard central battery system. The incoming order-wire junction from a central battery exchange (shown

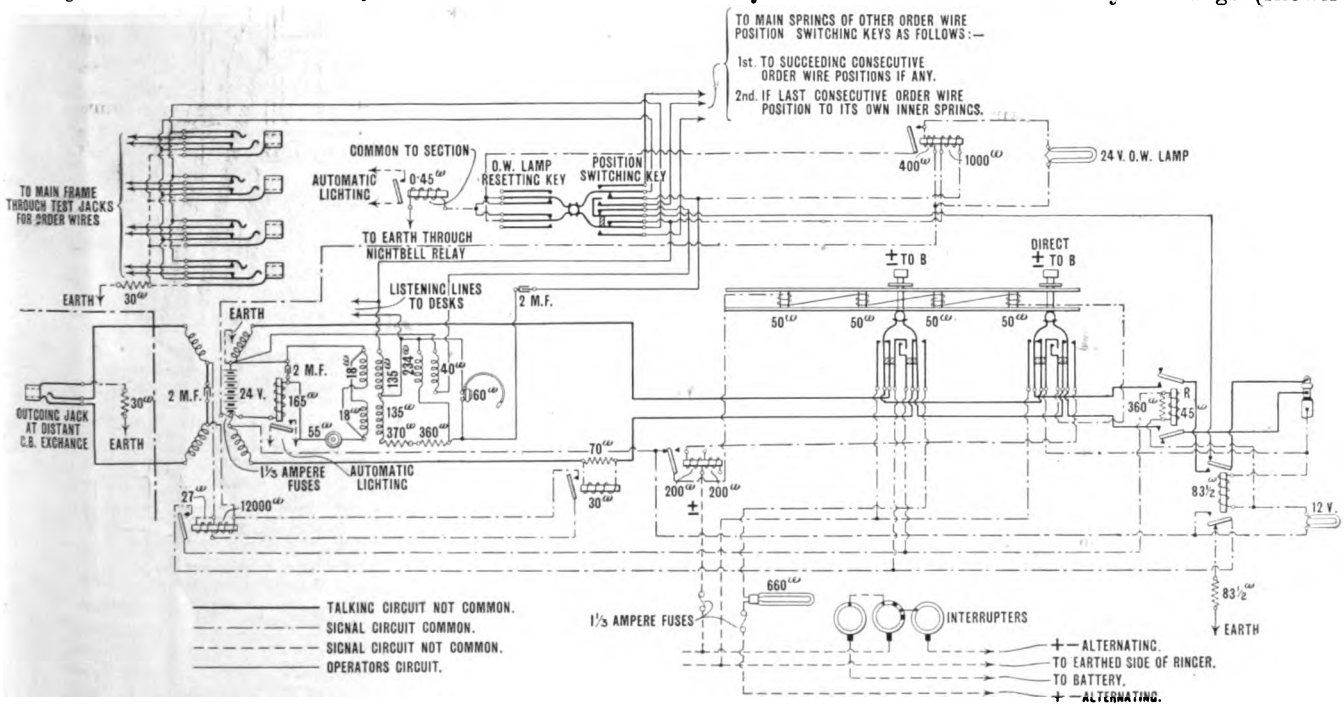

Fig. 2.—Incoming Order-Wire Junction Circuit.

in Fig. 2) differs from the previous circuits, however, in having two machine-ringing keys, one of which is arranged as a non-locking key for code ringing on party lines with more than two stations.

The party lines are operated in the following manner:—Associated with each party line are two multiple jacks, but only one answering jack and calling lamp. The answering jack and one of the multiple jacks are cross connected at the intermediate and main

Digitized by Google

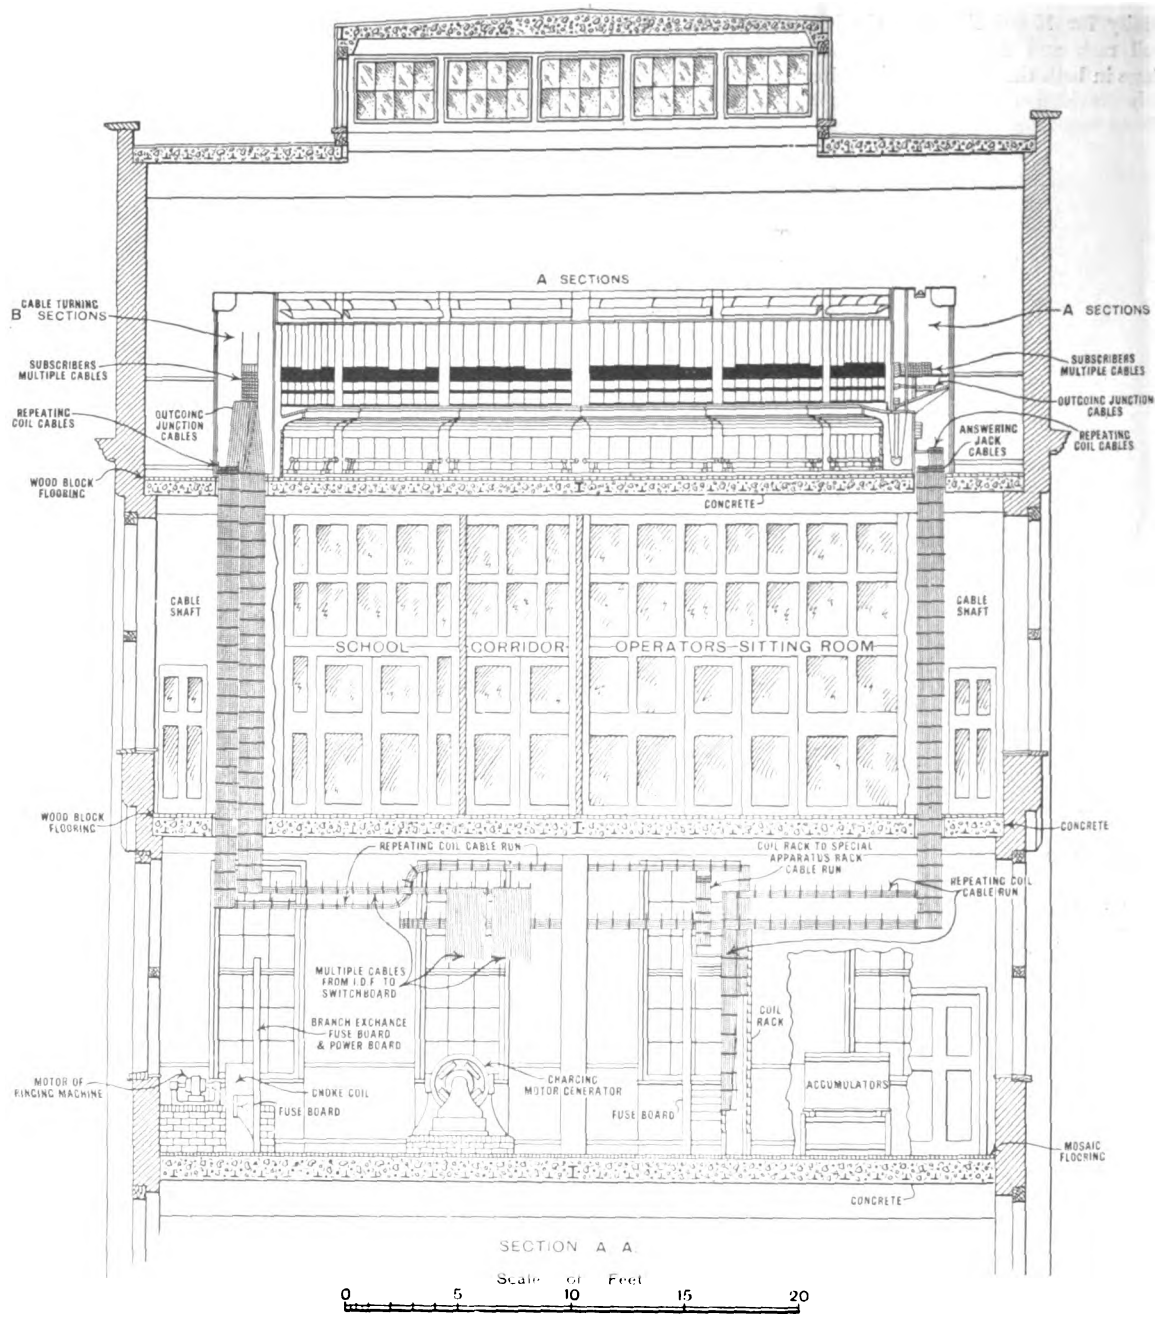

FIG. 3.—SECTION OF BUILDING.

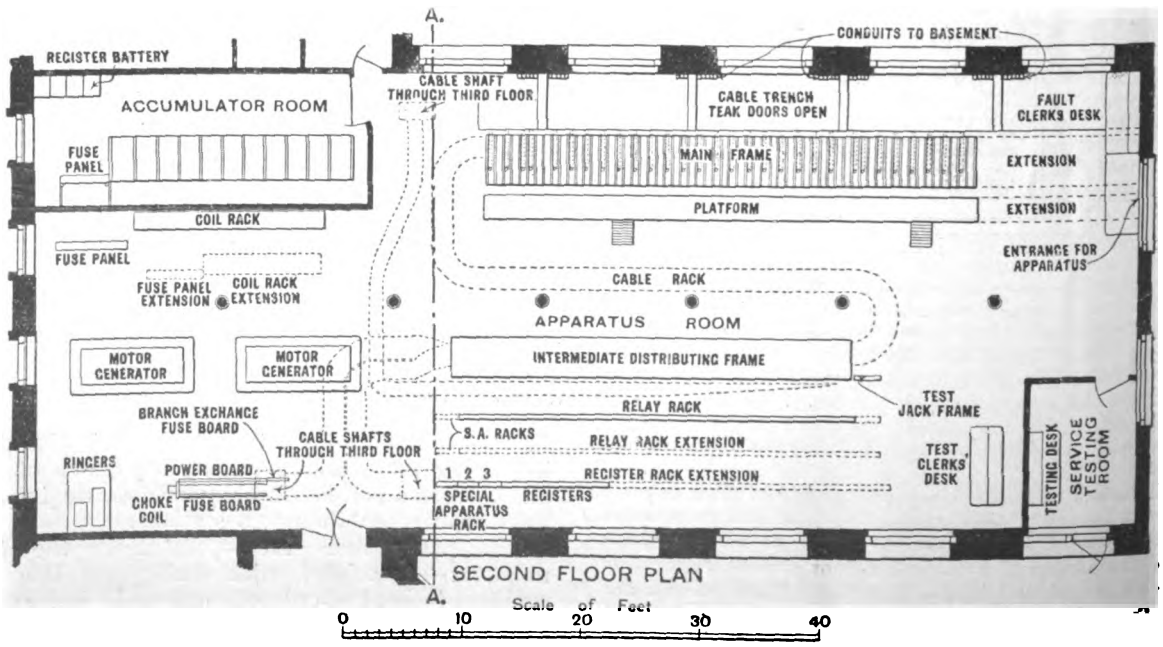

FIG. 4.—PLAN OF APPARATUS ROOM.

Digitized by Google

distributing frames in the usual manner; the second multiple jack is cross connected to the answering jack at the intermediate frame, but the A and B wires of the jumper are reversed at the horizontal side. This method of cross-connecting is shown in Fig. 5; it will be seen that an operator on one multiple jack rings over the A side of the line, and on the other multiple jack over the B side, in each case ringing the subscriber or subscribers on the one side only. The two subscribers on a two-party line will thus have two distinct numbers, which may or may not be consecutive.

The chief advantages of this system for two party-line working are:—(1) The party-line subscribers are rung by the operator with the same key and in the same manner as the direct-line subscriber; (2) as it is unnecessary for an operator to know she is ringing a party-line subscriber, the usual letters X or Y after the number are omitted, making simpler numbers; (3) no letter being necessary and the numbers of the two subscribers on one line being independent of each other, a party-line subscriber may take an exclusive line, or may change his place of business or residence in the exchange area, without changing his number; (4) more efficient use can be made of the line plant, for, if one subscriber ceases, a subscriber with a different number can be connected to the same outside line at once, instead of the line remaining spare for some months.

For party lines with four subscribers, only the first (on A positions), and to a small extent the fourth advantages apply, as code ringing must be used. The letters Y1, Y2 respectively are affixed to the numbers of the four subscribers; the letter indicates that code ringing is required, and the figure the number of rings which must be given. To prevent subscribers being called in error should the "B" operator commence to ring before the "A" operator at the distant exchange has taken up the junction and operated the relay *R*, Fig. 2, the latter is also operated by the inner springs of the code-ringing key.

With this system the number of multiple jacks for party lines is doubled, and therefore it will not pay to introduce this method of working in exchanges with a large proportion of party-line subscribers. Should a party-line subscriber ask for another subscriber on the same line, the operator is liable, unless special attention is paid to the supervision of party-line calls, to test the line and report engaged. Provision has therefore been made for a special tone test on the sleeve of the jacks when an operator has an answering plug in the answering jack, and is testing the multiple of the same line with the corresponding calling plug, but it has not been found necessary at present to bring this circuit into use.

The desk equipment comprises an exchange manager's, monitor's, and clerk-in-charge's desk, each with two positions, but the latter has one position only equipped.

The cables from the apparatus room to the switch room are carried by runs in three cable shafts through the third floor—one for the multiple cables to the A-sections, the second for

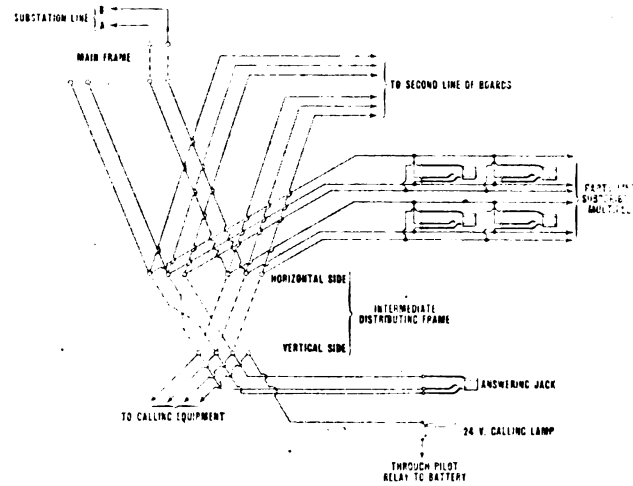

FIG. 5.—DIAGRAM SHOWING REVERSAL OF PARTY-LINE MULTIPLE CONNECTIONS ON THE I.D.F.

the multiple and repeating-coil cables to the B-sections, and the third for the answering jack and repeating-coil cables to the A-sections. The two latter are shown in the section of the building (Fig. 3). The cable shafts are designed so that there is sufficient space for men to work inside on all parts of the run, and a doorway in each shaft is provided from the corridor. The top and bottom of each shaft are packed with asbestos held in place by uralite below and teak above. The section also shows the positions of some of the cable runs in relation to each other and to the apparatus.

The building was constructed by Messrs. Sapcote & Sons, Birmingham, to the designs of Mr. Leonard Stokes. The telephone plant was supplied and installed by the Western Electric Company.

LOCAL NOTES

ABERDEEN: *Speed Indicators on Tramcars.*—With regard to the recent circular of the Board of Trade suggesting that speed indicators should be fitted to a certain proportion of tramcars on all systems for the purpose of training drivers in judging speed, the Tramways Committee recommend that no action be taken, on the ground that such indicators are not a success.

BLACKPOOL: *Electrical Exhibition.*—An Electrical Exhibition, organised by the Electricity Committee, was opened last week.

COLCHESTER: *Tramway Receipts.*—It is anticipated that the loss upon the tramway undertaking for the year ending this month will be as much as £4,000, against £2,900 last year. This result is largely due to the boycott of the cars by the public owing to the recent increase of fares, and the subsequent reduction of fares does not seem to have attracted the traffic back again.

DERBY: *Tramcar Accident.*—The trolley poles of two tramcars running in opposite directions on Friday, were by some means both running on the same wire. In the collision which occurred, the head of one of the poles was snapped off.

DUBLIN: *Tramway Men's Provident Fund.*—The report and statement of accounts for the year 1903 of the Dublin United Tramways Co.'s Employees' Provident Fund show that the total fund during the year amounted to £1,438, of which the Committee expended for sick benefit, medical aid, etc., to 382 members, and mortality allowances to the representatives of 13 members and four members' wives deceased, £1,198, leaving £240 available for dividend. Of this sum £213 was distributed amongst the members at the rate of 5s. per fully-paid member, and £27 was carried to next account.

Electricity Undertaking.—The Electric Lighting Committee have now reported upon the report recently prepared by the City Treasurer and City Accountant, in which they recommended that the prices to consumers would have to be raised in order to balance the receipts with the expenditure. Full particulars of this report were given in ELECTRICAL ENGINEERING for February 11th. The Lighting Committee now state that whilst admiring the labour involved in this report, they must to a large extent differ from the conclusions arrived at, and deprecate the course taken in calling for a report to be drawn up without consulting with the Committee. They express their great confidence in the future of the electric supply undertaking, which, in spite of great difficulties, now brings in a revenue from private consumers of £35.000 per annum, compared with £14.000 five years ago. At the same time the Committee make certain recommendations which will have the effect of temporarily increasing the rates charged to private consumers, and further recommend that the maximum demand system should be abolished.

FLEETWOOD: *Purchase of Supply Company.*—A Local Government Board inquiry was held last week into an application by the Corporation for sanction to borrow £21,500, mainly for the purchase of the undertaking of the Fleetwood & District Light & Power Syndicate.

HASLINGDEN: *The Tramways.*—Since the local tramway system was opened last September, there has been a loss upon the undertaking estimated at about £1,000 per annum. The Council anticipate that an improvement will take place when

Digitized by Google

through communication is effected with Rawtenstall. Meanwhile some staff rearrangements have been made which will bring about a saving of £150 per annum.

HESTON & ISLEWORTH: *Electricity Profits.*—The annual report of the undertaking, presented at the last meeting of the Council, stated that there was a net profit of £80.

HULL: *Electric Light Undertaking.*—In answer to a question last week, the Chairman of the Electric Lighting Committee stated that there would be no grant to the rates from the electric lighting undertaking this year, as no profits had been made. The committee, he said, gave the benefit to the consumer and not to the ratepayer.

LIVERPOOL: *New Trunk Telephone Exchange.*—A new trunk telephone exchange was opened at the Victoria Street Post Office last week.

LONDON: *London County Council Tramways.*—In answer to a question at the meeting on Tuesday, Mr. Whittaker Thompson, the chairman of the Highways Committee, said that the road alterations in connection with the further experiments with the G.B. surface-contact system in the Mile End Road were nearly completed, and an experimental car was expected to be running almost any day.

The report of the Highways Committee, recommending the purchase from the Metropolitan Electric Tramways Co. of the portion of the Paddington and Harrow Road tramways which is in the county of London, details of which were given in our last issue, was adopted.

The Highways Committee recommend that a special meeting of the Council be summoned in accordance with the provisions of Section 43 of the Tramways Act, 1870, in order that the Council may consider and decide whether they shall exercise their right to require the London United Tramways, Ltd., to sell to the Council the portions of the company's undertaking in London. The tramways purchasable are about 5½ miles in length, and are situated in Hammersmith. The purchasing powers come into operation this year.

Bethnal Green: Electricity Supply.—Bethnal Green has the distinction of being the only borough in the County of London which has no electric supply. The Works Committee recently received proposals to supply electricity in the borough from the Shoreditch and Stepney Borough Councils under the provisions of the London Electric Supply Act, 1908. The proposals were the result of concerted action by those authorities, which sought to undertake the supply and distribution of energy in the borough, the area of the same being divided into two parts for that purpose. The rates of charge suggested were those that respectively obtain in Shoreditch and Stepney. The Committee think it probable that a scheme can now be adopted to supply electricity in Bethnal Green at reasonable rates without any financial burden upon the ratepayers. They ask to be authorised to consider the desirability of taking steps to obtain such a supply and to obtain from various authorised undertakers schemes for the purpose.

OXFORD: *The Tramways.*—The General Purposes Committee have reported to the Corporation with regard to the tramway position, and recommend that efforts should be made to arrive at a compromise with the National Electric Construction Co.

PETERSFIELD: *Electric Lighting.*—The Council have passed a resolution deciding to apply for an electric lighting Provisional Order.

PUDSEY: *Assessment of Telephone Co.*—The Town Council have passed a resolution suggesting that the National Telephone Company's undertaking should be assessed according to the earning capacity.

SHEFFIELD: *Electricity* v. *Gas.*—The engineer to the Sheffield Gas Co., Mr. J. W. Morrison, in his address as President of the Manchester District of the Institution of Gas Engineers, made some reference to the competition between gas and electricity. He claimed that, in spite of reductions in the price of electricity and improved lamps, gas held its own still. A 60-c.p. inverted incandescent lamp, using 3½ ft. of gas per hour, cost in Sheffield ⅛d. per hour, or 4s. 8d. per thousand hours, compared with a 50-c.p. Osram lamp using 62 watts per hour, costing ¼d. per hour, or £1 0s. 10d. per 1,000 hours.

Smoke Abatement Exhibition.—Sir Oliver Lodge opened an exhibition at the Corn Exchange, Sheffield, on Monday, which has been organised by the Coal Smoke Abatement Society. The exhibition will continue until March 13th. The machinery exhibits include a large amount of electrical plant, in addition to mechanical stokers, gas engines, &c. The Sheffield Corporation Electric Supply Department have a stand, upon which a large number of new electric lamps and fittings, specially adapted for shop lighting, are displayed, as well as electrical heaters and other electrical apparatus.

SOUTH SHIELDS: *Tramway Intercommunication.*—The manager of the Corporation tramway system, having been asked to report upon the advisability of the Corporation cars running over the Jarrow system, has asked his committee whether it would pay to run their cars something like 6,000 miles per month, and be paid 3·6d. per car mile by the company. This latter is the price which the Corporation pay the company for running over the South Shields system, but the manager points out that this latter figure would not be justified in the case of the Corporation cars running to Jarrow, as there would not be the same inducement for large numbers of people to go to Jarrow as there is in the case of South Shields. The manager, however, has been asked to give the matter further consideration.

Tunnel under Tyne.—The Corporation has now definitely decided to withdraw absolutely from any connection with the scheme for constructing a tunnel under the Tyne. It will be remembered that the promoters of this wished the North and South Shields and Tynemouth Corporations to guarantee the interest on the 4 per cent. debentures of the undertaking, but, as Tynemouth and North Shields have withdrawn, the South Shields Corporation cannot see their way to accept the responsibility of guaranteeing the whole of the interest.

STOCKPORT: *Electricity and Tramway Profits.*—For the year to March 31st, the Electricity Department will hand over £2,000 in relief of rates, and the Tramway Department £5,000. These amounts are the same as were transferred last year.

WILLESDEN: *Bulk Supply Charges.*—Negotiations have recently been entered into with the North Metropolitan Electric Power Supply Co. in connection with a proposed reduction of the bulk supply charges. Four offers have within the last twelve months been made by the company and rejected by the Council, and finally the company, on February 4th, put forward a proposition based upon the assumption that the agreement would not be terminated before 1918, the rates of supply to be as follows:—(*a*) A fixed charge of 20s. per kw. of the maximum supply demanded per quarter. (*b*) For the first 400,000 units metered per quarter, £1,000. (*c*) All further units consumed at 0·4d. per unit. The Committee having considered the report of the sub-committee, directed the Clerk to inform the company that they were not prepared to recommend the Council to bind themselves for so long a period as fourteen years, and that they had accordingly instructed their Chairman, Clerk, and Electrical Engineer to negotiate further with the company.

YORK: *The Tramways.*—In pursuance of a requisition signed by five members, a special meeting of the Corporation was held on Friday, when a resolution was passed that a poll should be taken before obtaining tenders for the construction and lease of the proposed tramways.

The following scale has been fixed by the Electricity Committee for the supply to the tramways when constructed:—For the first 250,000 units per annum, 2d. per unit; in the excess of 250,000 and not exceeding 500,000, 1¾d. per unit; and for each unit in excess of 500,000 per annum, 1½d. per unit.

TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-stations, Mains, &c.

LEYTON.—The Engineer has been instructed to obtain quotations for cable to the total of six miles, which is the estimated amount required for the coming financial year.

LONDON: *Stepney.*—The Finance Committee of the London County Council recommend sanction to the borrowing of £10,000 for electric lighting mains, repayable within thirty years.

Woolwich.—A loan of £753 for electric lighting purposes is recommended by the Finance Committee of the London County Council.

MANCHESTER.—A Local Government Board inquiry was held on Saturday into an application by the Corporation for sanction to borrow the sum necessary to purchase a storage battery for the Dickinson Street power station.

ROCHDALE.—The Corporation require a water treatment plant for the electricity works. Particulars from the Electrical Engineer, and tenders by March 17th.

NEWFOUNDLAND.—The Canadian Trade Commissioner for Newfoundland, in his last published report, says the *Board of Trade Journal*, states that the promoters of the Newfoundland General Electric Co., intend to petition the Legislature for a charter under which a company is to be formed to light Bonavista, Catalina, King's Cove, and Trinity by electricity. In addition to electric lighting, the company propose to run an electric trolley line between Catalina and Bonavista, to erect a marine slip either at Catalina or at Trinity, and to supply electric power to such local factories as the company may find it feasible to establish.

WALTHAMSTOW.—Sanction has been received from the Local Government Board to borrow £877 for mains and house services, and £419 for meters.

Miscellaneous

BLACKPOOL.—An inquiry was held last week by the Local Government Board into an application by the Corporation for sanction to borrow £3,050 for the purpose of installing electrically-driven pumps in connection with the sea-water supply.

BOOTLE.—Tenders for electrical stores are required by March 20th. Particulars from the Town Clerk.

Digitized by Google

GREAT CENTRAL RAILWAY CO.—Tenders are invited for various stores during the twelve months ending April 30th, 1910, including electric light and telegraph materials.

GRIMSBY.—Tenders for the supply of arc lamp carbons during the coming twelve months are required by the 13th inst. Particulars from the Electrical Engineer.

HULL.—The Guardians of the Kingston-upon-Hull Incorporation for the Poor invite tenders by March 9th for the installation of electric power at the workhouse laundry. Particulars from the Clerk, St. Mary's Chambers, Lowgate, Hull.

LONDON: *London County Council.*—In connection with the construction of the tramways from Lewisham High Road to Forest Hill, the Highways Committee of the London County Council recommend that a portion of this, amounting to 1·14 miles of single track, should be put in hand at once. The estimates are as follows:—Track work, inclusive of rails, £18,330; cars, £1,900; cables, feeder pillars, &c., £1,830; cable ducts and laying thereof, £840; sub-station equipment, £40; making a total of £22,940.

Islington.—Tenders are invited for the supply of general stores for twelve months, including electrical fittings and sundries.

MANCHESTER.—The Tramways Committee invite tenders for the supply and delivery of steel tie-bars and fish-plates for tramway rails. Particulars from the General Manager, and tenders by March 9th.

NORTON: *Sewerage.*—A Local Government Board inquiry was held, on the 24th ult., at Norton, regarding a scheme of main and outfall sewerage for Norton, Stockton-on-Tees, per plans prepared by Messrs. D. Balfour & Son, civil engineers, Newcastle-on-Tyne. The sewage from the low-lying portion of the district is proposed to be carried to an underground storage tank, from which it will be pumped into the high-level sewers either automatically by electric motors, if the necessary power can be obtained, or by gas engines driving centrifugal pumps. There was no oposition to the scheme.

NOTTINGHAM.—The Tramways Committee invite tenders by March 11th for various stores, including overhead materials and electrical sundries. Particulars from the Town Clerk.

SOUTHAMPTON.—The Local Government Board is to be asked for sanction to borrow £600 for the purchase of meters.

Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. The sums in brackets indicate, not the estimated value of the electric light installation, but the estimated cost of the whole building.

LONDON.

E.—Additions, All Saints' School, Shortlands Road. Builder, J. & J. Dean, Knotts Green Road, Leyton.

N.E.—Schools, Greenleaf Road, Walthamstow. Architect, H. Prosser, High Street, Walthamstow, N.E.

S.W.—Handicraft centre, Park Walk, Chelsea. T. J. Bailey, Architect, L.C.C. Education Committee, Victoria Embankment.

W.—Cinematograph theatre. Harris and Gillow, 451A Oxford Street, W. (agents for letting site).

W.C.—Buildings, Sicilian Avenue, Southampton Row, Holborn. Architects, Worley & Armstrong, Aldwych Chambers, 170 Strand, W.C.

Building junction of Exeter Street and Catherine Street, Strand. T. Pocklington, 20 Lansdowne Road, Kensington, W.

PROVINCES.

ABERDEEN.—Addition, Royal Infirmary (£15,000). Kelly & Nicol, 367 Union Street, Aberdeen.

BELFAST.—Additions, Municipal Technical Institute. Architect, R. Stephenson, Royal Avenue, Belfast.

BRISTOL.—Extension, Public Museum. T. C. Yabbicombe, City Offices, Bristol.

BRIGHOUSE.—Baths. Borough Surveyor, Town Hall, Brighouse.

COVENTRY.—Wesleyan church. Crouch & Butler, Newhall Street, Birmingham.

DUDLEY.—Skating rink, Trindle Road. William Harper.

DARTFORD (KENT).—Additional workrooms, Darenth Asylum (£4,225). Engineer, W. T. Hatch, Metropolitan Asylums Board.

EAST STONEHOUSE.—Alterations to premises (£763) for the Guardians. Architects, Thornely & Rooke, 11 The Crescent, Plymouth.

EDINBURGH.—Almshouses (£10,000). Architect, H. Kerr, 62 Hanover Street, Edinburgh.

ISLEWORTH.—School, Twickenham Road. H. J. Barker, Secretary, Heston & Isleworth Education Committee.

JARROW.—Additions, Masonic Hall. Architect, J. H. Morton, 50 King Street, South Shields.

LIVERPOOL.—Additions, St. Edmund's School. Architects, Powell & Worthy, Lord Street, Liverpool.

MEXBOROUGH.—Rebuilding premises for the Barnsley British Co-operative Society, Ltd. Architect, H. L. Paterson, 19 St. James Street, Sheffield.

NORWICH.—Infirmary (£11,739). Architects, Morgan & Buckingham, 1 Upper King's Street, Norwich.

NORTHAMPTON.—New Buildings, Craven Street, for the trustees of St. Lawrence's Parochial Buildings.

New Music Hall and shops, Marefair, Horsemarket and Pike Lane. Builder, Mark Bromet, 12A Charterhouse Square, E.C.

SALFORD.—The Education Committee have decided to incur an expenditure of £400 on an electric light installation at the Technical Institute.

SOUTHAMPTON.—Chapel, lodge, and offices in new cemetery. J. A. Crowther, Borough Engineer.

SOUTH SHIELDS.—Y.M.C.A. premises. Architect, J. H. Morton, 50 King Street, South Shields.

TWICKENHAM.—School, Hartington and Napoleon Roads. H. J. Saunders, Secretary, Twickenham Education Committee.

WORKSOP.—Offices for Waterworks Co. (£1,699). Architect, A. H. Richardson, Market Place, Worksop.

TENDERS RECEIVED AND ACCEPTED

CANADA.—It is announced that further contracts have been placed by the Ontario Hydro-electric Commission for the construction of power transmission lines to Western Ontario.

DUBLIN.—The question of gas *v.* electric lighting has again been discussed with regard to the lighting of the North Union Workhouse. The Gas Company had offered to carry out the work for £600, whereas the Electric Light Committee of the Corporation estimated that the premises could be lighted with electricity at £445 per annum. The Electric Light Committee of the Union recommended that this latter tender should be accepted, and the Guardians have adopted this course.

EDMONTON.—The Guardians have accepted the tender of Child & Co., Willesden, for the supply of electric lifts at £1,039.

FARNWORTH.—The contract for the electrical fittings at the new Town Hall and public offices has been placed with Messrs. J. W. Singer & Sons, Ltd., of Somerset.

LAUNCESTON (TASMANIA).—It is stated that an agreement has been arrived at between the representative of Messrs. J. G. White & Co., Ltd., and the Council, for the granting of a tramway concession for 30 years.

LONDON: *Bermondsey.*—The Council have accepted the tender of the British Insulated & Helsby Cables, Ltd., at £47 10s., for the supply of one feeder pillar. Six firms tendered, the prices ranging from £24 15s. to £62 10s.

Hackney.—The Council has accepted the tenders of Chamberlain & Hookham, Ltd., and Ferranti, Ltd., for electricity meters at the following prices:—3 amperes, £1 16s.; 5 amperes, £2; 10 amperes, £2 10s.; 50 amperes, £2 14s.; 75 amperes, £3 3s.; 100 amperes, £3 3s.; 150 amperes, £4 4s.; 200 amperes, £7 15s.

Islington.—The Council has accepted the following tenders for annual supplies for the Electricity Committee:—Arc lamps, carbons, and globes, Sloane Electrical Co., Ship Carbons, Ltd., City Glass Co.; transformers and accessories, British Electric Transformer Co., Ferranti, Ltd.; meters and prepayment meters, British Westinghouse Co., Bat Meter Co.; cables, British Insulated & Helsby Cables, Ltd.; electrical sundries, lamps, brushes, arc lamp parts, &c., Cryselco Co., Ltd., Baxter & Caunter, General Electric Co., Heap & Johnson, Johnson & Phillips; cable, terminal, service, and network boxes and tapes, Callenders, British Insulated & Helsby Cables Co., Lucy & Co., Sykes & Sugden, Johnson & Phillips, Indiarubber Co., Ltd.

Metropolitan Asylums Board.—The tender of W. J. Fryer & Co. at £34 18s., for the supply of electric radiators for the operating-room at the Children's Infirmary, has been accepted.

SOUTHAMPTON.—The Electricity Committee have accepted the following tenders for the annual supply of cables:—W. T. Glover & Co., Ltd., class A, £65; class B, £233; class C, £313; class D, £251; Craigpark Electric Cable Co., Ltd., class E, £96; class F, £314; class G, £333; class H, £95; class I, £98; class J, £83; and class K, £81.

Electric Power in Canada.—A report from Halifax states that the Maritime Province Co. are applying for permission to dam the head of the Cumberland and Mines basins, and a number of rivers flowing into the Bay of Fundy, in order to utilise the heavy tidal flow for the generation of electric power for sale in New Brunswick and Nova Scotia.

Electrical Installation at Bentley Priory.—Some years ago this building was partly wired and supplied with approximately a 12-h.p. plant, but recently, on the change of occupiers, it was decided to electrically light the whole of the building, the contract for which was placed with Messrs. Stegmann & Co., of Clapham Junction, who have now just completed the work. The present supply is from a 20-kilowatt dynamo, belt-driven by a 28-h.p. gas engine with town gas supply, with an accumulator storage battery of 880 ampere-hours capacity as standby, and the usual complement of switchgear, &c. The lamps installed number over 600, and are all of the high-efficiency Osram type. The building is of great historical interest, having been from time to time the residence of various notabilities, especially during the reign of William IV. The firm inform us that they also have in hand, besides a number of country and town residences, a large contract for electrically lighting Messrs. Ilfords, Ltd., also Messrs. Garton Hill & Co.

Digitized by Google

COMPANIES' MEETINGS AND REPORTS

ASCOT DISTRICT GAS & ELECTRICITY CO.—The report for the year ended December 31st, 1908, shows a profit of £32 on the electricity account.

W. T. HENLEY'S TELEGRAPH WORKS CO.—The report for the year 1908 shows a net profit of £71,274. The amount available for dividends is £52,196, making, with £23,650 brought forward from last year, a total of £75,846. The directors have transferred £10,000 to the reserve account, and recommend the payment of a dividend on the ordinary shares of 15 per cent. free of income tax (of which an interim dividend of 5 per cent., less income tax, was paid on September 1st last), leaving a balance of £25,346 to be carried forward. The meeting is on March 1st.

At the meeting on Monday the report and accounts were adopted. Mr. Sidney Gedge, the Chairman, who presided, pointed out that notwithstanding the bad times from which all industrial concerns were suffering, their company had managed to hold its head well above water, and to declare not only the usual 15 per cent. dividend, but to pay it free of income tax. In addition, the company had ample funds, and had written off £10,868 for depreciation and machinery, against £6,762 last year. At the close of the meeting a resolution was passed instructing the directors to commission some well-known artist to paint the portrait of Mr. George Sutton, the Managing Director of the company, and further, to present him with a service of plate and a suitable address to commemorate the twenty-eighth year of his association with the business, the amount to be expended not to exceed £1,000.

LANCASHIRE UNITED TRAMWAYS CO.—The report for 1908, shows a gross profit of £15,116, and after meeting prior lien debenture stock interest, and deducting the loss for 1907, there is a balance of £1,904, which has been carried to depreciation account. The receipts have increased by £2,002, and the expenses have decreased by £1,053 compared with the previous year. The receipts per car mile were 7·70d., against 7·56d. in 1907.

At the annual meeting on Friday the report and accounts were adopted.

CAMBRIDGE ELECTRIC SUPPLY CO.—The report for 1908 shows a net profit of £5,211, after meeting debenture and other interest, and placing £1,500 to depreciation. An interim dividend of 2½ per cent. has already been paid, and a further dividend of 3½ per cent. is recommended.

The report and accounts were adopted at the meeting last week.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The report for the year ended December 31st, 1908, shows a total available for dividend of £34,158 6s. 11d. After deducting interest on debenture stock, other interest, and interim dividend paid on the 7 per cent. cumulative first preference shares, there remains a balance of £18,364. After meeting the final dividend on the 7 per cent. cumulative first preference shares, transferring £1,500 to depreciation account, £1,500 to credit of preliminary expenses, £792 to suspense account, and the payment of a dividend of 2½ per cent. per annum on the ordinary shares, the balance of £6,492 is carried forward. The meeting is on Monday.

At the meeting on Monday, the report and accounts were adopted. Mr. H. St. John Winkworth, the Chairman, who presided, stated that 266 new consumers had been connected during the year, compared with 182 in 1907, the total number of consumers now being 3,649. The total number of units sold was 3,303,827, which was an increase of about 12 per cent. over the figure for the previous year. The average price received was 2·88d. per unit, against 3·23d. per unit, a reduction which was largely due to the greater proportion of units sold for power purposes, and the reduction in sales for light owing to the extended use of metal filament lamps. On the other hand, the cost of production had been reduced from 1·32d. per unit to that of 1·16d. per unit. Under the conditions of the trust deed securing the debenture stock, no dividend could be paid upon the ordinary shares, he said, until certain sums had been set aside for depreciation. As there was little possibility under these conditions of paying a dividend on the ordinary shares for the next year, it was proposed to ask the debenture-holders to agree to some modification of the trust deed which, whilst providing for depreciation, would allow something for ordinary dividends.

BERLIN TRAMWAYS.—The report of the Grosse Berliner Strassenbahn for the year 1908 shows that the total receipts amounted to £1,925,000, an increase of somewhat more than 5 per cent. over those of the previous year. The total expenses were £1,080,000, or 56 per cent. of the receipts. Cost of electrical energy amounted to 21 per cent. of the expenses. After paying the percentages due to local authorities and setting aside certain amounts for renewal funds, &c., a sum of £497,000 remained to be divided. A dividend of 8¼ per cent. was paid, as against 8 per cent. for the previous year. The car-miles run during the year were 6·1 per cent. greater than in the previous year. The takings amounted to 8d. per car-mile.

TELEGRAPH CONSTRUCTION & MAINTENANCE CO.—The report for 1908 shows a net profit of £61,895 after meeting debenture interest. With the amount brought forward there is a sum available for dividend of £171,340. An interim dividend of 5 per cent. has already been paid, and a further dividend of 10 per cent. is recommended, leaving £104,110 to be carried forward.

At the meeting on Tuesday the report and accounts were adopted.

LANARKSHIRE TRAMWAYS CO.—The result of the December half-year's working shows revenue of £33,737 and expenses amounting to £18,300. After meeting contributions to local authorities, interest on debentures, &c., and adding balance brought forward from last half-year there is a balance of £17,937. Of this amount £7,500 has been placed to reserve for depreciation, and the directors recommend a 6 per cent. dividend per annum on the ordinary shares for the half-year. There is a balance of £865 carried forward. The traffic receipts for the half-year show a decrease of £1,186, as compared with the receipts for the corresponding half-year of 1907. It is intended to proceed immediately with the extensions from Hamilton to Uddingston and from Wishaw to Newmains. At the recent meeting the report and accounts were adopted.

YORKSHIRE (WEST RIDING) ELECTRIC TRAMWAYS CO.—The report for 1908 shows a net income of £36,385 after bringing in the balance of £8,509 brought forward from the last accounts. After meeting the debenture interest of the 4½ per cent. and 6 per cent. stock, and adding certain sums to reserve, a balance of £13,661 is carried forward.

NORTHAMPTON ELECTRIC LIGHT & POWER CO.—The report for 1908 states that, after adding £2,000 to depreciation account, and writing £200 off motors, and inaugurating a reserve fund with £500, there is an available balance of £1,870. After meeting the half-year's dividend on 5 per cent. preference shares there is sufficient to pay a dividend of 5 per cent. for the year on the ordinary shares, carrying forward £238.

The report and accounts were adopted at the annual meeting last week, and it was also decided to issue a further £10,000 of ordinary shares for the purpose of installing new generating plant to the extent of 1,000 h.p.

CROSSLEY BROS. CO.—After meeting the interest on the 5 per cent. preference shares, and an interim dividend of 5 per cent. on the ordinary shares, there is a balance for the year 1908 of £53,181. It is proposed to pay the full dividend on the preference shares for the second half-year and 3 per cent. per annum on the ordinary shares (making 4 per cent. for the year), carrying forward £34,541.

At the meeting on Friday the report and accounts were adopted. The Chairman, Mr. Kenneth Crossley, stated that the result of the year's working, namely, a 4 per cent. dividend, compared with 11 per cent. in recent years, was unsatisfactory, and the directors did not wish to minimise their disappointment at having to recommend this smaller dividend. The causes which led up to this state of affairs were, he said, due to serious trade depression, and the temporary slump in the motor-car business. In answer to a few questions, the Chairman stated that they were very full up with orders for gas engines from 100 to 300 b.h.p., but there was very little doing with engines of 500 b.h.p. and upwards.

TORONTO ELECTRIC LIGHTING CO.—At the annual meeting last week it was stated that the revenue during 1908 was £237,447, the largest during the existence of the Company. The Chairman, Sir Henry Pellatt, assured the shareholders that they need have no fear that the revenue of the Company will in any degree be diminished by the supply offered by the Government Hydro-electric Commission. He further added that opinions from the most eminent counsel in Toronto were to the effect that in 1919, in the event of the City exercising its option to purchase, it must buy the Company's undertaking as a going concern.

BUENOS AYRES GRAND NATIONAL TRAMWAYS CO.—At an extraordinary general meeting held last week, the provisional agreement for the sale of the Company's undertaking to the Anglo-Argentine Tramways Co. was passed, with some dissentients, and a poll was demanded.

DUBLIN UNITED TRAMWAYS CO.—At an extraordinary general meeting last week, it was decided to increase the capital of the Company by 10,000 ordinary shares of £10 each.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—At the annual meeting on Wednesday last week, the report and accounts given in our last issue were adopted. Lord Suffield, who presided, said that the larger profit this year was mainly due to the economical working of the Central Electric Supply Co. Referring to the effect of metal filament lamps upon the revenue, the Chairman made some reference to the heavy rates paid by the London electric supply companies. So far as the Westminster Company was concerned, in 1898 they paid rates to the value of £3,517, or 5 per cent. of their total capital expenditure, and although they were now only making half the

Digitized by Google

profit per unit they were making 10 years ago, they were actually paying 50 per cent. more per unit in rates. If the rates in 1908 had borne the same proportion to the profits as they did in 1898, they would have paid £10,000 less, and he thought that they could fairly claim that they were making a contribution of at least £10,000 to the rates of the district they served.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—The report and accounts given in our last issue were adopted at the meeting on Wednesday last week. Sir Edgar Speyer, who was in the chair, expressed his unqualified satisfaction at the result of the year's working, for whereas Sir George Gibb had estimated a deficit for 1908 of £54,000. this had, in fact, only been £12,000. The reason for this was that the three tube companies affiliated to the Underground Company had gone ahead in the most remarkable way. The District Railway Co. had also made very considerable progress, and the only disappointing undertaking with which they were connected was the London United Tramways Co., which was suffering very severely from motor-'bus competition. The estimated deficit upon the Underground Company for 1909 was £91,000, but in the light of their experience during 1908 he was of the opinion that this figure would be considerably reduced.

MANSFIELD & DISTRICT TRAMWAYS CO.—At the annual meeting on Friday the report and accounts were adopted. The receipts for 1908 amounted to £18,628, compared with £17,312 for 1907. After payment of debenture interest and the interim dividend on the 6 per cent. cumulative preference shares to Dec. 30th, 1908, the sum remaining is £1,800. The directors have transferred £1,200 to depreciation and redemption of debentures, the balance being carried forward. The number of passengers carried exceeded those of the previous year by nearly a quarter of a million. The extension known as the Crown Farm Colliery extension will in all probability be put in hand shortly.

NORTHALLERTON ELECTRIC LIGHT CO.—The report for 1908 shows a net profit of £218. With the amount carried forward from the last account, there is a balance of £236, which has been brought to reserve fund for depreciation.

BLACKPOOL & FLEETWOOD TRAMROAD CO.—At the annual meeting on Friday the report and accounts were adopted. There is a balance on the half-year's working, after providing for debenture interest, of £10,804, and a dividend of 9 per cent. was recommended. The number of passengers carried during the half-year was 1,716,182, and the receipts from all sources amounted to £22,293. The chairman, in referring to the large expenditure on law costs, namely £289, pointed out that this was in connection with the dispute between the company and the various Councils through whose area their line ran, upon the question of rating.

MATHER & PLATT.—At the annual meeting last week the report and accounts given in our issue for Feb. 18th were adopted. Mr. John Taylor, who presided in the absence of Sir William Mather, who was on a visit to Egypt, said that for the first time in his business experience he found every branch of trade depressed in every country in the world. There was usually a bright spot somewhere, but at present it was hard to find. The business of the company last year was again largely foreign, but he was pleased that their gas engines were proving very successful, and they were just completing, or had in hand, gas engines for Russia, India, Australia, and West Africa. They were now able to supply gas engines up to 2,000 h.p., and the Board hoped for large developments in that department.

NEWCASTLE & GATESHEAD WATER CO.—At the annual meeting last week, it was stated that the revenue of the company might be permanently affected by the increasing use of electricity instead of steam power in the company's area.

NATIONAL TELEPHONE CO.—At the ordinary general meeting on Thursday the report and accounts given in our last issue were adopted. Mr. George Franklin, the president of the company, who was in the chair, stated that the rate of progress had been checked, partly by circumstances, such as the trade depression and cotton strike in Lancashire, and also to some extent by the necessary restriction of capital expenditure owing to the approaching termination of the company's licence. The severity of the trade depression was emphasised by the fact that there had been no less than 28,281 cessations of telephone stations on the company's system during the year compared with 25,115 in 1907. After allowing for all cessations, however, 28,791 stations had been added to the system during 1908. During the same year the company had added to its London system 10,325 stations and the Post Office 6,067 stations. Hitherto it had been the practice to lay down plant in advance of requirements, but in view of the approaching purchase of the company upon the basis of plant value, it was evident that the time must come when the company could only provide such plant as would bring revenue during their remaining years, and it had been decided that this should be their policy between now and the year 1912, unless the negotiations with the Postmaster-General to get over the difficulty were successful.

ABERDEEN: SUBURBAN TRAMWAYS CO.—At the meeting on Friday the report and accounts given in our last issue were adopted. With regard to the dispute between the company and the Corporation as to the price at which current shall be supplied for working the tramways, the chairman stated that the Board of Trade had not yet fixed the arbitrator for determining this matter.

NOTTING HILL ELECTRIC LIGHT CO.—At the annual meeting on Tuesday the report and accounts given in our last issue were adopted. Sir William Crookes, who was in the chair, stated that arrangements were being made for co-operating with the Metropolitan Electric Supply Co. so far as the northern part of their district was concerned, under the powers of the London Electric Supply Act passed last session.

NEW COMPANIES

LA PLATA ELECTRIC TRAMWAYS CO.—Registered on Feb. 4th, with a capital of £450,000 in 200,000 preference and 250,000 ordinary shares of £1 each, to adopt an agreement with La Plata and Ensenada Tramways Co., Ltd., and the liquidator thereof, to acquire or construct, equip, maintain and work tramways, railways, and lines of telegraph, telephone, or other means of communication in Argentine Republic or elsewhere, and to carry on the business of tramway and railway proprietors, carriers of passengers and goods, electricians, electrical engineers, proprietors of motor omnibuses and other conveyances, &c. First subscribers: W. F. Hamilton, K.C. (late director of Buenos Ayres and Belgrano Electric Tramways Co., Ltd.), J. S. Harmood-Banner, M.P. (director of British Insulated and Helsby Cables, Ltd.), W. T. Western (chairman of Rosario Electric Co., Ltd.), and W. Murray Wilson (late chairman of Union Tramway Co., Monte Video). Registered office: 52 Moorgate Street, E.C.

PACIFIC RADIOTELEGRAPH CO.—Registered on Feb. 5th, with a capital of £60,000, to acquire powers for the construction, maintenance, and working of a system or systems of inter-communication by means of radio-telegraphy between the islands of the Pacific Ocean and the territories of Australia and New Zealand, and to carry on the business of a telegraph, telephone, submarine cable, and wireless telegraph company in any part of the world. First directors are the Earl of Crawford, J. T. Arundel, Sir Sidney H. C. Hutchinson, Kt., and J. W. O. Hamilton. Registered office: 54 Old Broad Street, E.C.

P.-V. SYNDICATE.—Registered on February 5th, with a capital of £1,000 in £1 shares, to carry on the business of a telephone, telegraph, and electric light, heat and power supply company. Private company. The provisional directors are P. B. Potter and A. K. Sterne. Registered by Slaughter and May, 18 Austin Friars, E.C.

GORING & STREATLEY ELECTRIC LIGHT & POWER CO.—This company was registered on January 22nd, with a capital of £3,000 in £1 shares (1,500 preference), to acquire the Goring Electric Light undertaking, and to carry on the business of suppliers of electricity for light, heat, and power, electric engineers, &c. Private company. The number of directors is not to be less than two nor more than five; the first are F. A. Dyster and J. W. Jennings. Qualification, 10 shares. Remuneration as fixed by the company. Registered office, The Works, Goring Hill, Goring-on-Thames, Oxford.

SOUTHAM & WOOD.—This company was registered on January 25th, with a capital of £2,000 in £1 shares, to carry on the business of designers, manufacturers of and dealers in electric light apparatus, conduits, dynamo machines, lamps, fittings, accessories, &c. The subscribers are:—J. C. Wood, Sheffield House, 162 Oxford Street, W., engineer; A. D. Southam, Sheffield House, 162 Oxford Street, W., engineer. Private company. The joint managing directors are A. D. Southam and J. C. Wood. Qualification, £100. Remuneration as fixed by the company. Registered by Alfred H. Atkins, Ltd., 27-8, Fetter Lane, E.C.

NEW PUBLICATIONS

"Electric Lamps." By Maurice Solomon. (London: Archibald Constable & Co., Ltd.) Price 6s. net.

"A Handbook of Wireless Telegraphy: Its Theory and Practice." By Dr. J. Erskine-Murray. Second Edition. (London: Crosby Lockwood & Son.) 10s. 6d.

"Electricity in Factories and Workshops. By A. P. Haslam. (London: Crosby Lockwood & Son.) Price 7s. 6d. net.

Improvements on the Underground Railways.—In order to save passengers' time on the London "tube" railways, various new devices are being tried. At Dover Street and Earl's Court stations a lift-signalling system, electrically connected with the automatic signalling system, has been adopted experimentally. A bell in the lift rings on the approach of a train, and the interval before its arrival is just sufficient to enable the lift to descend and the passengers to reach the platform. Illuminated indicators over the lifts, which are lit up five seconds before the lift reaches the top, have also been htted in several stations.

Digitized by Google

PARLIAMENTARY INTELLIGENCE

PRIVATE BILL PROCEDURE.—The following Bills have been read a second time in the House of Lords :—City of Bath Electric Supply; Liverpool Corporation; Southport and Lytham Tramroad (abandonment).

The following Bills have been read a second time in the House of Commons :—North Metropolitan Electric Power Supply; Oxford and District Tramways; Preston, Horley, and Horwich Tramways; Bury Corporation; and Wallasey Tramways and Improvements.

A select committee of the House of Commons will sit on March 11th to commence consideration of a group of Bills, which includes the North Metropolitan Electric Power Supply Bill.

STANDING ORDERS.—The Standing Orders Committee have decided to dispense with the requirements of the Standing Orders in respect of petitions against the Central London Railway, Edgware & Hampstead Railway, North Metropolitan Electric Power Supply, and the L.C.C. Tramways and Improvements Bills.

LONDON POWER SUPPLY.—The President of the Board of Trade has given notice of his intention to introduce into the House of Commons the Bill constituting the London County Council the purchasing authority in respect of the West End electric supply companies not dealt with in the London Electric Supply Act of 1908.

APPOINTMENTS AND PERSONAL NOTES

Mr. William Hartley, Electrical Mains Superintendent for the Nelson Corporation, has been appointed Chief Assistant Mains Superintendent to the Rochdale Corporation.

The salary of the Mains Superintendent to the Croydon Corporation, Mr. E. A. Fella, has been increased from £190 to £200 per annum, the maximum being fixed at £230, rising by annual increments of £10.

Mr. Brooks, at present Chief Inspector upon the Brighton Corporation Tramways, has been appointed Traffic Manager.

The Harrogate Corporation require a canvasser (see an advertisement).

A works manager is required by the Stirling Telephone & Electric Co., Ltd. (see an advertisement).

A chemist for a paint and varnish works is required (see an advertisement).

Probable Action re Failure to Supply in Dundee.—The solicitors of Messrs. J. & A. D. Grimmond, a large jute firm, have written to the Dundee Town Council, intimating that the Council will be held liable for the losses sustained by the firm due to the failure to supply electrical energy on and after the contract date of Feb. 1st. It appears that an agreement between Messrs. Grimmond and the Electrical Department was passed by the Council in August last, in which it was stated that the supply would be commenced on Feb. 1st. At that time it was expected that the new generating station would be ready to supply on that date, but for various reasons the building is not yet completed, and it is possible that the supply will not be commenced until July next. It is said that the delay in completion is partly due to the fact that the work was taken out of the hands of the Electrical Engineer and handed over to the City Engineer and the Works Department, who had already far too much work. Several difficulties in construction have also arisen.

Comparative Costs of Illuminants.—In the latter part of his third Cantor lecture at the Royal Society of Arts on Monday evening, which concerned means of illumination other than electricity or coal gas, Mr. L. Gaster gave a table showing the comparative costs of different illuminants. The figures were reduced to charges of 4d. per unit for electricity, and 2s. 6d. per 1,000 cubic feet for gas, and included lamp, mantle, or carbon renewals. The carbon filament lamp headed the list with a cost of 1s. 2d. per 1,000 candle-power hours; metal filament lamps averaged about 5d, and the various methods of gas lighting came next. The lowest figure was that for the flame arc, namely, 1d. per 1,000 c.p. hours; the high-pressure gas system was somewhat dearer. However, as Mr. Gaster pointed out, comparative tests, made under exactly similar conditions and with units of the same size, for the different methods of illumination were not available, and therefore the above figures were only approximate. With regard to the temperature of the light-giving body, the lecturer stated that at a temperature of 2,000° C. (at which the metal filament was run), an efficiency of about 2 per cent. was possible only, but that if a temperature of 7,000° C. could be reached, then half the energy employed would be converted into light. He also showed several curves of the distribution of energy in the spectrum, which demonstrated the fact that most of the energy from modern illuminants was given out in the form of heat rays. On the other hand, the curve for the fire-fly (a case of phosphorescence) showed that all the rays emitted were within the limits of 0·4 μ and 0·7 μ, and were light rays. Finally Mr. Gaster dealt with the colour of the light from the various illuminants.

MISCELLANEOUS CITY NOTES

BROMPTON & KENSINGTON ELECTRIC LIGHT CO.—A dividend of 11 per cent. per annum is recommended on the ordinary shares for the half-year, making 10 per cent. for the year, carrying £2,000 to reserve, £8,000 to depreciation, and carrying forward £9,400.

SOUTH METROPOLITAN ELECTRIC LIGHT AND POWER CO.—Warrants for dividends on the company's ordinary and 7 per cent. first preference shares for the year and half-year, ended December 31st, 1908, respectively, have been posted.

COMPANIES STRUCK OFF REGISTER.—The names of the undermentioned joint stock companies have been struck off the register :—Electric Light & Power Co. of Japan, Electric Motive Power Co., Ltd., Epstein Electric Accumulator Syndicate, Ltd., Nuneaton & District Light Railway Co., Ltd., and Welsh Electric Traction Co., Ltd.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton (last week, £59 5s. to £59 15s.).

AGENCY.—Messrs. J. & H. Grevener, of Eldon Street House, London, E.C., have appointed the following agents :—Messrs. Thompson & Ramsay, Castle Chambers, 55 West Regent Street, Glasgow, as agents for Scotland; Messrs. Laidler Ritchie & Co., Ltd., Nutsford Vale Works, Pinkbank Lane, Longsight, Manchester, as agents for Manchester and district; Messrs. The Robinson & Hands Electrical Co., Ltd., 54 Barwick Street, Birmingham, as agents for Birmingham and Midlands. Inquiries to the above firms will meet with prompt attention.

DINNER.—The annual dinner of the Chelsea Electric Supply Company's Cricket Club was held at the Pier Hotel, Oakley Street, W.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the St. Albans & District Electric Supply Co., Ltd., will be held at the Electrical Federation Offices, Kingsway, London, on March 31st, at 3 p.m., to receive the liquidator's account of the winding up.

High-voltage Tantalum Lamp.—A 200-volt tantalum lamp will no doubt be put on the British Market by Messrs. Siemens Bros. shortly, as the Siemens & Halske A.-G., of Berlin, have already placed one on the German market. The new lamp, which can be obtained for all pressures between 200 and 240 volts, and in 32 and 50 c.p. sizes, consists of two tantalum wire "zig-zag" cages, mounted one above the other on the same glass pedestal. Both pear-shaped and spherical bulbs are supplied. The length of a pear-shaped 32-c.p. lamp is 5·9 in., and that of a 50-c.p. lamp 6·1 in., and the maximum diameters are 2·56 in. and 2·95 in. respectively. An average life of 800 hours, and an efficiency of from 1·5 to 1·7 watts per candle, are claimed.

London County Council Tramways and Income Tax.—With reference to the action taken by the London County Council against Inland Revenue authorities concerning the amount of income tax which should be payable upon the South London tramways (ELECTRICAL ENGINEERING, Feb. 18th, p. 164), the Finance Committee of the County Council recommend that, after careful consideration of the matter, the Council should not appeal against the decision of the High Court. They are carefully considering the course to be taken as regards the claims for depreciation for the years subsequent to 1903-4, and will report on this matter at a later stage.

"Electrical" Fires in the City of London.—In his annual report, the City Coroner, Dr. Waldo, states that during the past year 134 fires were officially notified by him, as against 145 in 1907. Of these, the cause of the fire was determined in 117 cases, the cause in the remaining 17 cases being unknown. Of the 12 fires which he had referred to the City Electrical Engineer as being possibly due to electrical causes, seven only were found to be the result of defective electrical arrangements. Dr. Waldo comments on the success of the system of personal investigation on the spot of the fire undertaken by him, and suggests that the City of London Fire Inquests Act, according to which these "inquests" are carried out, should be extended to the Borough of Southwark, where fires, especially dock fires, are serious and frequent.

The Cable Communications of the World.—Two interesting articles dealing with submarine cable telegraphy, from the pen of Mr. Charles Bright, F.R.S.E., appear in current reviews. One of these, in the *Fortnightly Review*, is entitled "Imperial Telegraphy at a Popular Tariff," and discusses at some length various aspects of company and State ownership of cables, and the possibility of eventual penny-a-word telegrams throughout the British Empire. The cables of the Empire also form the principal theme of another article by Mr. Bright, published under the title of "Communication by Cable," in the March *Westminster Review*.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 25th, 1909

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

28,652/07. **Compensated Auto-transformer.** H. M. HOBART, F. B. CRAMER, and E. COAD. This is a combination of an auto and an ordinary transformer, a few secondary turns of the transformer being connected in series with each section of the auto-transformer. The voltage drop in any one circuit due to the loading of any other, in the case of the transformer, is equal and opposite to that in the case of the auto-transformer. Thus the pressure across any one section of the combined transformer will be unaltered by change of load on any other section; the pressure across each section will vary with the load on that section. Four claims, six figures.

4,695/08. **Conduit Clips.** J. J. RAWLINGS. The "buckle" clip or fastener for fixing tubing or wiring conduit to walls, described and illustrated in ELECTRICAL ENGINEERING, Vol. IV., p. 739, is manufactured by the Sun Electrical Co., Ltd., under this patent. It consists of a metal strip punched in the centre and provided with an elongated opening and a tongue for fastening round the tube. A wood screw, or a dowel-pin with a metal screw, is used for fixing it to the wall. Four claims, seventeen figures.

4,977/08. **Enclosed Flame Arc Lamp.** A. D. JONES. In order to enable impregnated carbons to be used in an enclosed arc lamp, means for preventing the deposit of the ash on the glass globe must be provided. According to the present invention, the globe is composed of two parts, an upper metal cap provided with external corrugations to assist cooling, and a lower transparent part provided with an outer globe to prevent cooling. A rapid circulation of the fumes past the arc without local eddy currents is produced, and a white reflecting deposit forms on the upper metal cap, while the lower transparent part of the globe is kept hot and clear. The globe is so shaped that a single vortex ring sweeps the whole inner surface, and it can be adapted for either vertical or converging carbons. Two claims, two figures.

9,481/08. **Automatic Electric Heater.** T. J. RORKE and E. RORKE. A resistance wire heater for automatically controlling the temperature of rooms, &c., is described. With the aid of electrically operated switches and a mercury thermometer relay, the two heating elements are put in parallel, or one only is used, or both are connected in series, according to the temperature of the room. Four claims, six figures.

10,590/03. **Manufacture of Metal Filaments.** BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)*. According to this invention, zirconium oxalate is used as a binder for forming a filament from powdered tungsten. As zirconium oxalate is gelatinous, no further binder is required. On heating to a high temperature, the filament sinters into a homogeneous body of tungsten and zirconium oxide, and has a high specific resistance. Four claims.

16,621/08. **Traction Motor Control.** BRITISH THOMSON-HOUSTON Co. *(Allgemeine Elektricitäts-Ges.)*. A system of control is described in which the separate motors of a multiple unit equipment are independently and successively started and accelerated in order to avoid current shocks. Five claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad.

Summaries of some of the more important of these patents will appear in our next issue.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: BRITISH THOMSON-HOUSTON Co., ROBERTSON, and HOLDEN [Power transmission] 3,284/08; HELLER [Conduits] 22,719/08.

Dynamos, Motors, and Transformers: AMPHLETT 2,838/08.

Electrometallurgy and Electrochemistry: COWPER-COLES [Electrodeposition of iron] 3,160/08; MIELE [Deposition of metallic coatings] 5,198/08; FALK [Battery] 17,886/08.

Ignition, Electric: WILKINS and MUIRHEAD & Co. [Magneto apparatus] 12,302/08; STEPHENS [Internal combustion engines] 13,378/08.

Incandescent Lamps: HOWELL, 3,388/08.

Instruments and Meters: ROBINSON [Prepayment meters] 3,646/08; HOOKHAM [Meters] 12,009/08.

Storage Batteries: MARCHAL [Charging apparatus] 3,494/08.

Switchgear, Fuses, and Fittings: MORCOM and MORRIS [Choking coils] 4,361/08; MARKS *(Societa Anonima Italiana Gio Ansaldo Armstrong & Co.)* [Control of pumps] 6,461/08; ELECTRIC AND ORDNANCE ACCESSORIES Co., HALL, and MUELLER [Circuit-breakers] 7,382/08; JACK [Crane control gear] 8,467/08; IDE [Push-switch lamp-holder] 12,592/08; SIEMENS BROS. DYNAMO WORKS, LTD. *(Siemens Schuckertwerke-Ges.)* [Fuse-holders] 1,510/09.

Telephony and Telegraphy: FALKENTHAL [Transformer for telephones] 2,824/08; MUND [Wireless signalling] 3,154/08; BRADBURN [Telephone systems] 4,246/08; BEECH [Printing telegraph] 5,042/08.

Traction: MEYER [Safety-guards for tramcars] 20,473/08; MAYSON and EDGAR [Life-saving catchers] 24,118/08.

Miscellaneous: WELCH and HARVEY FROST & Co. [Vulcanising apparatus] 3,250/08; DE HAAS [Electrically operated water-closet flushing apparatus] 3,710/08; BUTTERWORTH and VEEVERS [Flash-light signalling] 4,910/08; DAVIS and BERRY [Thread singeing machine] 21,425/08; PAGE *(Universal Electric Welding Co.)* [Welded wirework fences] 25,391/08.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

NODON [Recovery of tin from lead alloys] 7,706/08; FAGERLUND [Electrically operated valves] 2,740/09.

Applications for Amendment

Further particulars and instructions as to procedure in opposition to amendment will be found in the Official Journal of the Patent Office of Feb. 24th, 1909.

12,739/02. **Manufacture of Incandescent Lamps.** A. SWAN (General Electric Co., U.S.A.). It is desired to alter the wording of the first two claims in this specification in order to define more clearly the scope of the invention. The patent is for a lamp base or cap in which the metal shell is interlocked with a glass button uniting the metallic contacts, when the glass is in a fused condition. Machines for performing this operation are described in the specification.

8,851/07. **Variable-speed Polyphase Motor.** H. A. MAVOR and MAVOR & COULSON, LTD. This specification, an abstract of which was published in ELECTRICAL ENGINEERING, Vol. IV., page 294, describes an induction motor in which both primary and secondary elements rotate. The patentees desire to amend the drawings, as the connections between the slip-rings and the motor elements are shown incorrectly.

Opposition to Grant of Patents

Opposition to grant on the following applications has been entered.

14,554/08. **Vulcanising Apparatus.** P. ALLMAN and G. W. LEESON. This invention relates to electrical apparatus for vulcanising tyres, cable coverings, &c. The heating element consists of a network sheet of resistance wire interwoven with asbestos threads and covered with woven asbestos.

19,311/08. **Manufacture of Tungsten Filaments.** SIEMENS & HALSKE AKT.-GES. The process described consists in first reducing a mixture of nickel tungstate and tungstic acid or a plastic tungsten compound, so that an intimate mixture of nickel and tungsten is obtained. Rods of this mixture are ductile, and can be rolled or drawn into filaments. The nickel is afterwards expelled by heating the filaments in a vacuum. Further particulars of the process were given in ELECTRICAL ENGINEERING, January 7th, 1909, p. 21.

Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: J. H. O'DONNELL [Wire-drawing machine] 22,822/01; W. C. JOHNSON and J. W. BASS [Braided covering for cables] 24,755/02.

Dynamos, Motors, and Transformers: C. D. ABEL *(La Société Anonyme pour la Transmission de la Force par L'Electricité)* [D.-C. to A.-C. rotary transformer] 21,543/95; BRITISH THOMSON-HOUSTON Co. and H. M. HOBART [Transformer for three-wire systems] 26,040/97.

Ignition, Electric: A. G. BLOXAM *(A. Schoeller)* [Magneto generator] 24,302/03.

Incandescent Lamps: F. LEHNER [Manufacture of carbon filaments] 20,461/00.

Switchgear, Fuses, and Fittings: BRITISH THOMSON-HOUSTON Co. *(General Electric Co., U.S.A.)* [Two-way switch] 24,286/03.

Telephony and Telegraphy: J. T. ARMSTRONG and A. ORLING [Electro-capillary receiving apparatus] 24,516/03.

Traction: L. KRIEGER [Electrically-propelled vehicles] 24,941/96; THE WESTINGHOUSE BRAKE Co., LTD. *(G. Westinghouse)* [Brakes] 20,447/00; C. DE KANDO [Compressed-air multiple-unit control system] 22,658/01; G. G. BLEYNIE and T. DUCOUSSO [Railway signalling] 22,280/03.

Miscellaneous: W. DUDDELL [Microphone-oscillograph combination for recording sound] 24,546/02.

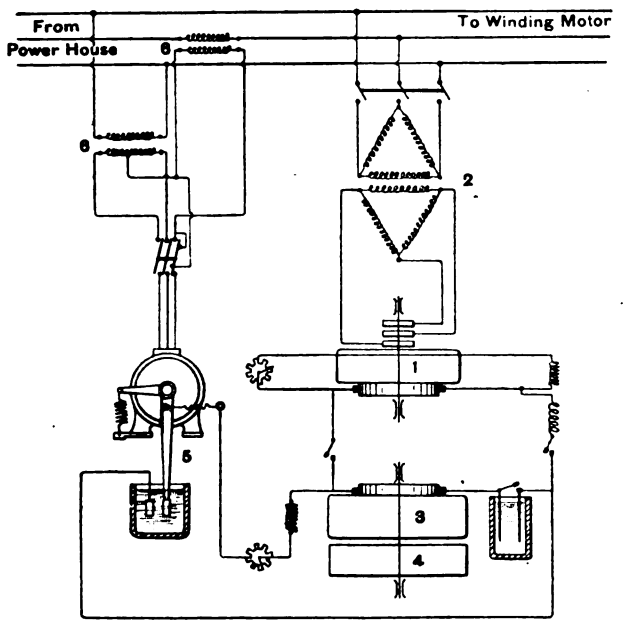
FLYWHEEL LOAD EQUALISERS

IN a Paper read on Tuesday, February 23rd, before the Manchester Local Section of the Institution of Electrical Engineers Mr. J. S. Peck (British Westinghouse Co.) referred to the advantages possessed by flywheel sets over batteries for load equalisation, and proceeded to describe some systems which had been developed.

Speaking first of continuous-current equalisers, he referred to the load equaliser made by the Lancashire Dynamo & Motor Co. (Kelsall and Warburton patents). This consists of a direct-current machine coupled to a flywheel, and an automatic regulator. The machine has three field windings—a shunt winding, a winding in series with the armature for overcoming the armature drop, and a special winding in series with the circuit on which the load is to be equalised. This special winding is shunted by a resistance, the amount of which is controlled by the regulator. When the load on the mains falls below the average, the decreased current through the special winding tends to cause the machine to motor and speed up the flywheel, thus taking power from the mains. As the flywheel increases in speed and the current falls, the regulator cuts out the resistance in shunt to the special winding until the speed-limit is reached. When the load exceeds the average value, the process is reversed.

The Lahmeyer Co. patented in 1902 a load-equalising system in which two direct-current machines (1 and 2) are employed, coupled together and to a flywheel. The large machine works with a constant field, and the other with a variable field. The two are connected in series across the mains. When the voltage of 2 is at its maximum and opposed to that of 1, the voltage across the latter is a maximum and equal to that of the line plus that of 2. Under this condition the flywheel is running at maximum speed. If a load above the average comes on the circuit, the voltage of 2 is decreased by means of an automatic regulator, which inserts resistance into the shunt field winding of 2, and the voltage across 1 is thus reduced. 1 therefore begins to generate. In order that it may continue to generate as the speed of the flywheel falls, the voltage of 2 must be gradually reduced to zero and then increased to a maximum in the opposite direction. When this condition has been attained, the flywheel will have reached the minimum speed at which generation can take place. When the load on the system falls below the average, a reverse process with reference to the voltage of 2 is carried out, the flywheel is speeded up, and power is taken from the mains. A similar system is employed in some of the Lahmeyer electric winding plants.



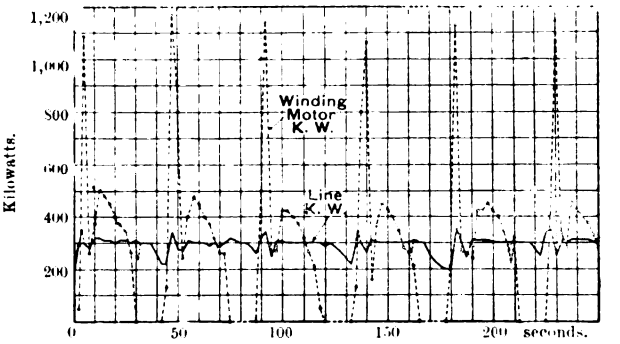


FIG. 1.—BRITISH WESTINGHOUSE ROTARY CONVERTER EQUALISER SYSTEM.

1. Rotary converter.
2. Transformers for supplying rotary.
3. Flywheel machine.
4. Flywheel.
5. Automatic regulator.
6, 6. Series and shunt transformers for controlling 5.

There are two general classes of alternating-current load equalisers—those in which a rotary converter or synchronous motor-generator set is installed for changing from alternating current to direct current, and a direct-current machine with flywheel for receiving or delivering power through the converter or motor-generator; and those where an alternating-current machine is direct coupled to a flywheel, and the machine so arranged that it can act as motor or generator at any speed within the desired range.

The best-known equaliser of the first class is the Westinghouse converter equaliser, which was first suggested by Mr. Rudolf Braun. A 500-h.p. equaliser is in operation at the mari-

(Readings every 2½ seconds.)

FIG. 2.—GREAT WESTERN WINDER.

(Tests of January 20, 1909.)

time pit of the Great Western Colliery Co. in South Wales. The arrangement is shown diagrammatically in Fig. 1. 1 is the rotary converter, 2 the three-phase transformer supplying it, 3 the direct-current machine, 4 the flywheel, and 5 the automatic regulator. When the load on the mains is light, the field of 3 is weakened, and the flywheel speeds up. When the load is heavy, the field of 3 is strengthened, and energy is returned to the line through 1. The rotary is provided with a series as well as a shunt winding. The two act in opposite directions when energy is being stored in the flywheel, and in the same direction when energy is being delivered by the flywheel. By making the shunt field rather strong, the rotary will work at approximately unity power factor when it is delivering direct-current power, and with a leading power factor when delivering alternating-current power. Thus it tends to compensate for the wattless current taken by the load. It can be used if desired without a series winding. A series winding was also placed on the flywheel machine, and connected in opposition to the shunt winding at discharge, the object sought being to prevent violent fluctuations in the charge or discharge rate due to sudden movements in the regulator, but as the regulator was provided with a rather stiff dash-pot, it was found that the best results were obtained by cutting out the series winding and working with the shunt winding only. The field resistance is of the liquid type, and arranged to give a very wide range with a small movement. The resistance is controlled by a three-phase induction motor, which is supplied from transformers in the main feeder.

Very excellent equalising results are obtained, as will be seen from the curves in Fig. 2, which were taken during the official tests on the complete plant. The equaliser is set to maintain a load of 300 kw. on the line, while the average for the time during which the readings were taken was about 294 kw., which accounts for the reduced load taken by the equaliser set toward the end of each decking period. The peak loads on the motor are over 1,100 kw., while the maximum output from the line is about 350 kw. The necessity for an equaliser is apparent from the curves.

Some details of the equipment and illustrations of the Great Western winder were given in an abstract of a Paper by Mr. G. Hooghwinkel on page 185 of our last issue.

It is often desirable to operate a rolling mill or winding engine by means of a very slow-speed induction motor from a 40- or 50-period circuit. If a speed of 60 revs. per min. is required, the motor must have approximately 100 poles on a 50-period circuit, and 80 poles on a 40-period circuit. The cost of a motor with such a number of poles is very high, while its efficiency is poor and its power factor so low as to almost preclude its use. To overcome this difficulty, and at the same

Digitized by Google

time to provide a load equaliser, the author has devised the arrangements shown in Fig. 3. This scheme is somewhat similar to the converter equaliser of Braun, except that the rotary is replaced by a motor converter, and the winding or mill motor supplied from the connections between the rotor and the direct-current armature of the motor converter. When the load on motor 1 is below the average, the machine 4 acts as a motor and speeds up the flywheel. When the load on 1 is heavy, 4 becomes a generator, and supplies alternating current to 1 through machine 3. At the same time 2 also supplies alternating current to 1, so that the power for driving 1 comes partly from the flywheel and partly from the line. Thus motor 2 need be large enough to supply only the average load of the motor 1, the peaks being taken care of by the flywheel through 4 and 3. 4 may be compound wound, or it may be run with a very stiff field in order to compensate for the magnetising current taken by the motor 1. The great advantage of this system is that it permits motor 1 to be operated at a frequency much lower than that of the line. One objection to this system is that the motor cannot be operated if the motor converter is disabled, though it could be operated at a reduced output without the flywheel machine.

In a Paper read two years ago before the Manchester Local Section of the Institution of Electrical Engineers (see ELECTRICAL ENGINEERING, Vol. I., pages 343 and 440), Mr. A. P. Wood described two equalising systems in which alternating-current machines were coupled direct to the flywheel, so that no conversion from alternating to direct current was required. In the first system two induction motors with different numbers of poles are coupled together and to a flywheel. To speed up the

flywheel, one motor is used and the other cut out. For returning power to the mains the motors are connected in cascade. The objections to this system are the large magnetising currents and the heavy rheostatic losses in the controller. In the second system the rotor of an induction motor is coupled to a flywheel, and both primary and secondary are arranged to rotate. When primary and secondary rotate in the same direction the flywheel reaches a speed greater than the normal synchronous speed of the motor. If, then, the primary is slowed down and gradually brought up to speed in the opposite direction, the motor will be running above synchronism and will deliver power. The speed of the primary is controlled by an auxiliary motor. The power factor of this system is much better than with the other; mechanical difficulties appear to make the system impracticable for large sizes.

The author has devised a system which he believes possesses a number of advantages. Its use is limited, however, to systems of low frequency. It employs one or more single-phase commutator-type machines. The motors are direct coupled to a flywheel, and arranged so that they can act as motors or as generators at any speed within the desired limits. It is well known that a single-phase series machine may be run as a generator, and if the field is excited by alternating-current, an alternating current of the same frequency will be generated by the armature; but this voltage will be almost at right angles to the voltage impressed on the field. Consequently, the field of the machine should be supplied with a voltage approximately at right angles to that of the circuit to which its armature is connected. Fig. 4 shows one way in which the system may be operated on a two-phase circuit. Two single-phase machines, 1 and 2, are coupled together and to a flywheel. The armature of 1 is supplied from phase A and its field from phase B.

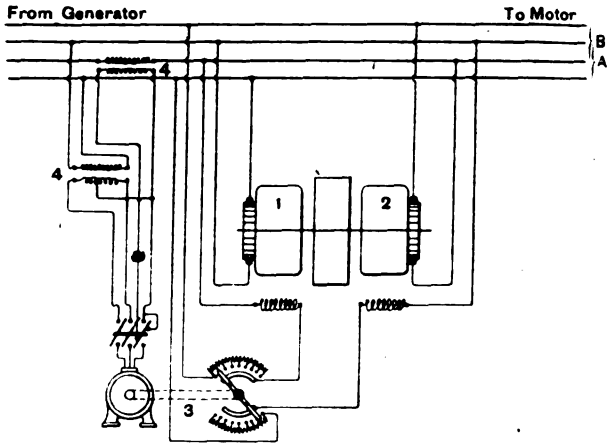

FIG. 4.—LOAD EQUALISING BY MEANS OF SINGLE-PHASE COMMUTATOR TYPE MACHINES.

1 and 2. Single-phase flywheel machines.
3. Automatic regulator.
4, 4. Transformers for supplying 3.

Similarly, the armature of 2 is supplied from phase B and its field from phase A. The field voltages are controlled by means of the automatic regulator 3.

The current for magnetising the fields of a single-phase machine is considerable, and as it is practically wattless, it has an effect upon the power factor of the line. This objection is overcome by exciting the field from an alternator driven by a synchronous motor. This arrangement is shown in Fig. 5, where 5 represents the exciting alternator, 6 the synchronous motor, and 7 a small direct-current machine for exciting the fields of the synchronous machines. An arrangement is provided for shifting the stator of 6 circumferentially with reference to the stator of 5, in order that the phase of the voltage of 5 may be shifted with reference to that of the line, thus permitting the single-phase machines to deliver leading currents to the line to compensate for lagging currents taken by other apparatus. To reduce the size of the exciter sets, the alternating exciter may be connected in series with the line, and

arranged so that its voltage may be added to or subtracted from that of the line.

For three-phase circuits two transformers may be used with Scott connection for changing from three-phase to two-phase,

Digitized by Google

and two motors employed, or three motors may be used, one supplied from each phase. The fields may be excited by a three-phase alternator, or from the line through transformers connected to give the proper phase relation between field and armature.

When considering the advisability of installing a load equaliser, the following points will probably prove the determining factors: Nature of load; capacity of generating station, and regulation of system.

The flywheel equaliser is suitable only when the peak loads are high and of short duration. When the generating station has ample capacity for dealing with heavy peak loads, the use of a flywheel equaliser need not be considered, but where the station cannot stand the peak loads, an equaliser may prove much cheaper than additional generating plant. Although the generating station has ample capacity for supplying the peak loads, the effect of these loads upon the regulation of the system may be so bad as to make a flywheel equaliser very desirable.

DISCUSSION.

Mr. MILES WALKER (British Westinghouse Co.) commented on the fact that the commutating machine seemed to have the best characteristics for this class of work; but there was a tendency to do away with it, and to use an induction motor. We wanted, however, a method of making the induction motor change its speed or start up without either the rheostat or the commutator. It was possible to change the speed of an induction motor through a wide range by changing the voltage of the rotor by means of an exciter having a commutator, and although the exciter had to deal with the whole current, it did not have to deal with the whole voltage, and there would seem to be an advantage in that. In Mr. Wood's system, a polyphase exciter might be used with the induction motor, so as to be able to change its speed without a rheostat. This would probably make a fairly efficient load equaliser, which would work at high as well as at low frequencies.

Mr. H. W. WILSON, in comparing battery and flywheel methods of power equalisation, said the great difficulty with a battery was the heavy depreciation. His firm recently installed a flywheel load equaliser in a case where a battery and a so-called reversible booster had been in use for about three years. At the present time the battery is entirely destroyed. From his own experience he had found that a flywheel load equaliser did everything that the battery would do, and did it more satisfactorily. The cost of an equipment such as the author's was much less than the cost of a battery and reversible booster, and the depreciation was obviously very much less. In a particular case he mentioned where a flywheel set had replaced a battery, there was no doubt that the efficiency of the flywheel load equaliser system was very much higher. There were cases where the installation of an equaliser near the load led to a considerable saving in cables.

Mr. V. A. H. M'COWEN (Chief Electrical Engineer, Salford Corporation) thought that the best place to fix an equaliser was not in the generating station, but in the remoter districts, where there were abnormal peaks. It might be a most desirable apparatus in connection with small tramway loads in reducing the necessary plant to meet that demand.

Prof. C. F. SMITH (Manchester Municipal School of Technology), after referring to the excellent slides used by Mr. Peck in the further illustration of his Paper, said that it was interesting to notice how much similarity there was in the auxiliary machinery employed in connection with the two types of load equalisers—the flywheel and the storage battery. The arrangement of series boosters, differentially-wound motors, &c., shown in the early part of the Paper bore a remarkable similarity to the corresponding diagrams for a battery-booster regulating installation. He said that Mr. Peck appeared to have discovered a use for a much-neglected machine, the shunt A.-C. motor. The difficulty with a shunt A.-C. motor was that the current in the field circuit lags very much behind the terminal voltage, and when the power factor of the armature circuit was high, there was a large difference of phase between the field and the armature current, and consequently a low torque. If, however, it was arranged that there was a small current in the shunt circuit, possibly adding a resistance so as to bring the power factor up comparatively high, a very good torque in the motor could be obtained over a considerable range of speed. He suggested that by using a shunt winding of many turns, it might be possible to dispense with the special exciter, especially on a three-phase circuit, where a choice of phases for the supply is available for giving the desired phase relation.

Mr. EUSTACE THOMAS looked forward to some simplification in the switching arrangements of these systems, and asked whether more might not be done in the direction of making the generating plant itself its own flywheel equaliser, to make the flywheels work over a greater range of speed, and to supply some of the energy now supplied by an equaliser separately run.

Mr. E. C. MCKINNON (Chloride Electrical Storage Co.), in speaking of the merits of battery and booster systems, pointed out that a battery would yield its output just as rapidly as a flywheel load equaliser up to the capabilities of the booster. He did not think that Mr. Peck was correct in stating that a flywheel load equaliser was more efficient than a battery. It was true that the efficiency of a battery on a long continuous discharge is about 75 per cent., but, working on a fluctuating load, and only giving out a small portion of its maximum output, it gave an efficiency from 85 to 90 per cent. Mr. McKinnon also mentioned some facts in connection with the case spoken of by Mr. Wilson, which showed that the battery which had been displaced had hardly been given a fair chance.

Mr. J. S. PECK, in reply, after speaking of the good working results obtained at the Great Western Colliery, expressed agreement with Mr. M'Cowen as to the desirability of placing the load equaliser near the load to be equalised. The A.-C. machine in his system was really a shunt machine, but in design and construction it was practically identical with a series compensated motor. The use of flywheels on the generators, as suggested by Mr. Thomas, was generally unsuitable with alternating currents, as it would entail variations in frequency. It might be possible with D.-C. machines with an automatic voltage regulator, to permit the speed to drop; but this would require a large margin in the field, since a maximum voltage would be required when the speed was below normal. Regarding battery discharge rate, the idea he had meant to convey was that a battery was not suitable where it had to be fully charged and completely discharged in the course of a few seconds.

GAS ENGINES v. STEAM TURBINES

Resumed Discussion in London

THE discussion on Messrs. Andrews & Porter's Paper, "The Use of Large Gas Engines for Generating Electric Power," was resumed in London last Thursday. The Paper, in an abridged form, together with a report of the first day's discussion, was published in our issue of February 18th, and a report of the discussions in Dublin and Manchester appeared in our last issue. It will be remembered that the authors gave the estimated costs of an 8,000 kw. generating station alternatively with steam and gas plant, and arrived at the conclusion that with coal at 12s. per ton and a load factor of 24 per cent., the gas plant was more economical than the steam plant.

Mr. H. A. HUMPHREY said that, although some 15 years ago dynamo-makers had refused to guarantee a machine if direct-coupled to a gas-engine, he had then obtained excellent results, although there were plenty of troubles and the repair bill was heavy. In general, he could endorse many of the statements made and the figures given by the authors. With regard to the cyclic irregularity, it was necessary for the electrical engineer to be familiar with the shape of the turning-moment curves, not only for full load but for part load, and to see how these curves were affected by the large inertia effects which came into play. With this object in view, he had prepared some cyclic irregularity and angular deviation curves for actual gas-engines, and these would be printed in the journal of the institution. There was no difficulty in designing gas-engine alternator sets to run in parallel. The efficiency of the boiler, he continued, was nearer 70 than 80 per cent.; when forced, it was less, and when banked, the waste was considerable. The gas-producer, on the other hand, was more efficient, more responsive to demands, and less wasteful when idle. Worked in conjunction with an ammonia recovery plant, it yielded an amount of sulphate of ammonia generally exceeding in value the total cost of the coal. He knew of no limit to the overload of a gas-producer, except that in which so much air and steam were forced through, that the coal was lifted out with the gas. The cost of producer fuel should not be more than that of boiler fuel. The South Staffordshire Mond Gas Co. paid an average price of 6s. 9d. per ton for nearly 30,000 tons of coal for use in producers, including carriage and unloading; the average calorific value was 12,000 B.Th.U. per lb. Producer gas had been supplied under pressure from a central station at Dudley Port for four years through many miles of underground distribution pipes without interruption, and no deposit had been found in the pipes. The ideal station would be, he thought, a combination of gas-producers with gas-turbines. Experiments with gas-turbines had been disappointing, but he had been making experiments which promised a large measure of success in rather a different direction. In his apparatus the gas explosions forced water into an air vessel and put it under pressure; this pressure was afterwards utilised by a water-

Digitized by Google

turbine. The explosions took place in contact with a column of water, and there was no piston. The four strokes of admission, compression, expansion, and exhaust were all unequal, as theory demanded, and expansion went down to atmospheric pressure. With a small apparatus of only a few horse-power, he had obtained a water horse-power for 2 lb. of cheap bituminous coal, and in a large plant he hoped to reduce this by one-half. With regard to gas-engines driving alternators, he said that close governing was a mistake, and that a speed variation of 6 per cent. between no-load and full-load was better for parallel running than a variation of only 2½ per cent. Finally, he had found a rigid coupling better and safer than any form of spring coupling.

Mr. J. S. Highfield (Chief Engineer, Metropolitan Electric Supply Co.) said that he was satisfied that the difficulties in running gas-engines were at the present moment distinctly greater than those with steam-turbines; incidentally, reciprocating engines were still less difficult to run than steam-turbines. The reason, he thought, was that there were very few men familiar with the running of gas-plants, and, further, manufacturers were still feeling their way in the matter of design. Consequently, it would be a mistake for engineers to apply the gas-engine at the present time on a very large scale to power-station use. For a lighting load in districts where coal was cheap, an engineer would be taking unnecessary risks if he put in gas-engines. On the other hand, if a large supply had to be given to chemical or other works, with an 80 per cent. load factor or more, then the gas-engine might be considered. It was only necessary to see Mr. Allen's plant at Western Point to appreciate that gas-plants could be run with bituminous coal. Mr. Allen had taken out the whole of his steam-plant, and replaced it with gas-engines which were using about 1·7 lb. of coal per kilowatt hour. Approximately 7s. 5d. per ton in bye-products was obtained. Remembering that coal was the dominating factor in this problem, he thought that gas-engines must come into use, and that it was simply a question of time. For purely central-station work, however, gas-engines should be used only in part in the first instance. With regard to the London supply problem, he had taken out figures and found that, of the plant installed, a fraction of sufficient capacity to run one-tenth of the whole London load as it was at present actually supplying 40 per cent. of the total output, and that one-half of the plant was only employed to supply 7 per cent. of the total output. Therefore, the proper way to introduce the gas-engine would not be to put up a huge gas-station running at a moderate load factor, but to bring in a certain proportion of gas-driven plant which should be run continuously at full load, and gradually to alter the design of the steam plant so that it could be steamed up rather more quickly than at present, and to reduce the stand-by losses as far as possible. It was not possible to get men used to running gas-plant, and, consequently, the troubles in the early stages would necessitate more stand-by steam-plant to take the place of the gas-engines when they failed. These troubles would probably exist for about the first twelve months, but would gradually disappear. For these reasons he urged gas-engine advocates to be extremely careful only to put up plant where good results were certain, otherwise they would do a great deal of harm to this development in engineering.

Mr. E. G. Sehmer (Messrs. Erhardt & Sehmer) said he did not agree that the overload capacity of the gas-engine was only about 10 per cent. to 12 per cent. Modern engines would give this continuously, and for shorter periods considerably more—even 20 per cent. Whilst in Germany they had not had much experience with producers, owing to there being so much blast-furnace and coke-oven gas; yet he had made tests with a class of fuel which could not be used under boilers, and had obtained good results with it in producers. One producer had run on a mixture of coal, slate, and refuse for 10 months, and had given about 120 B.Th.U. per lb., and he would not hesitate to use this gas. He agreed with previous speakers that 12s. per ton for gas-producer coal was too high; coal at half this price was being used for this purpose with satisfactory results. One speaker had expressed the opinion that 1,000 h.p. was the limit per cylinder for a gas-engine. As a matter of fact, his firm had built about 12 engines in which the horse-power per cylinder was 1,600 B.H.P., and they were now designing a tandem engine of a total of over 8,000 h.p., or over 2,000 h.p. per cylinder. He would be quite prepared to guarantee that the cost of repairs in a case like the one taken in the Paper would not exceed £2,000 or £2,500, including everything. It had also been urged that the price of gas-engines was too high; the reason for this was that gas-engine builders had spent an enormous amount of money in experimenting, and this had to be got back in some way. But prices had come down very quickly, and soon the difference between the price of steam-engines and gas-engines would not be considerable. The authors had, however, taken rather high figures in their estimates of capital cost, and he would be ready to take any amount of orders at considerably lower prices.

Professor R. Threlfall, F.R.S. (Birmingham University), said that the authors had apparently relied upon getting 90 lbs. of ammonium sulphate per ton of coal from coal at 12s. per ton. He thought that South Lancashire was the only district in England where this result would be obtained. It was not made apparent in the Paper whether any allowance was made for raising the steam to work the plant; perhaps reliance was placed on the regeneration of the boilers which took the heat from the gas engines. Those engines coming on for a short time, however, would not make any steam, because the boilers would not get hot. With regard to repairs, he thought the figure of 6d. per ton on the producer plant was a good deal too low. It had occurred to him that it would be wiser to make the piston rods and stuffing-box of the finest tool steel in order to get them as thin as possible, and thus reduce the temperature of the outer surface to the lowest possible point. He also thought that the compression in the engines should be reduced. He was not sure whether the cylinder should be all in one piece or in several pieces, but he did feel that any engineer who was going to run a gas-engine plant would be well advised to make financial provision for breaking a cylinder every few years; in ordinary working he should say three or four years, though in an electric light station the life might stretch to four times this amount.

Mr. J. E. Dowson (the Dowson Economic Gas & Power Co.) said that the general feeling at present was that although British makers were prepared to supply gas engines up to 1,000 h.p., they would not accept the responsibility of going beyond this; but he did not see why this should be so. At present, at any rate, it would be prudent for electrical engineers, mainly on the ground of reliability, to stop at units of 1,000 h.p. Again, with this size unit it was not necessary to have a recovery plant, which involves very heavy expenditure and occupies a large amount of floor-space. With a 1,000-h.p. unit, bituminous coal of almost any kind that was non-caking could be used, or even coke, and considerable economy would be obtained compared with steam plant. The question of stand-by losses in steam plant was very important, and he hoped that many central station engineers would investigate the matter in order to get at the actual losses. He did not agree with Mr. Humphrey as to the low efficiency of boiler plant; he had always understood this to be really the most efficient end of a system.

Mr. A. M. Taylor (Birmingham Corporation Electricity Supply Department), part of whose remarks were in the form of a written communication, drew attention to the authors' method of estimating the true cost of the "additional" units. According to Willans' law, the steam consumption was equal to a certain constant amount plus an amount dependent on the load. This latter amount corresponded to about 14 lbs. of steam or 2 lbs. of coal (10,000 B.Th.U.) per unit generated for a large steam turbine, whereas the actual consumption worked out to some 3 or 4 lbs. of coal per unit. The difference could only be accounted for by constant losses, and, he thought, the true cost in coal of the "additional" units was independent of the running plant load-factor, and could be taken at about 2·2 lbs. for large turbine units and say 2·75 lbs. for reciprocating engines of about 500 kw. capacity. Speaking with reference to Fig. 3 (Electrical Engineering, February 18th, p. 170), Mr. Taylor asked whether the authors had considered the possibility of reducing the number, and increasing the overload capacity, of the gas-engine units by combining them with batteries of accumulators, placed preferably in rotary-converter or motor-converter sub-stations. Thus three gas-driven units, each of 2,000 kw. capacity, and two battery units, each of the same capacity, could be installed. Then, with one gas set laid up for repairs and one set broken down, the load had to be taken up between the two battery units and the remaining gas engine for two hours. This involved a 45 per cent. overload on the two batteries and a 10 per cent. overload on the gas engine. If the batteries were put in for a 3½-hour rating, they would do this overload for two hours. The batteries and accessories would cost about £11 per kilowatt, as against some £14 for the gas plant plus £6 for feeders and rotaries = £20 total, and the saving in fixed charges would more than suffice to pay the maintenance and depreciation rate twice over. As regards coal, the area dealt with by the battery in normal working would be that above the 4,000-kw. line, or say some 3,600,000 units, out of a total of 21,000,000. Allowing for losses in batteries and auxiliaries, the supplying of these units would involve an extra 1,800,000 units, which, however, being merely a make-up load, would be chargeable at the rate of "additional" units, and therefore would only account for some 900 tons of coal. This was turned into a gain of 900 tons by the fact that the other 3,600,000 also became make-up units, and thus saved 1,800 tons—a net gain of 900 tons. The engine hours could be reduced to some 9,500 as against 17,450, and the producer hours from 35,000 to say 20,000, which two items would jointly account for a saving of some 1,700 tons of coal per annum, allowing for the fact that the units were larger than those proposed by the authors. The net saving in coal would, therefore, be some 2,600 tons per annum; the capital saving would be some £36,000, or, in the case of a transformer sub-station, £24,000. The annual net saving on fixed charges alone (ex. interest) would be at least £4,000 per annum; the whole amounting, on a 24 per cent. load factor and with coal at 12s. per ton, to a saving of 0·10d. per unit generated or 25 per cent. off the authors' estimate for gas plant.

Mr. G. L. Addenbrooke said that he had been pulled up on the question of working producers at low loads; they were very

Digitized by Google

rarely efficient at anything less than half-load. On the question of steam- v. gas-stations, the authors' figures were, he thought, too high for the steam-plant, and they had postulated conditions rather against the plant than for it. A debt of gratitude was owing to the authors for their diagram of losses in steam-plant. Tests of the combined efficiency of whole plants were apparently never made, or, at most, only in a very approximate manner. At the same time, he did not quite agree with the way in which the diagram had been drawn. As he had stated in his recent lectures before the Royal Society of Arts, he thought there was room for 25 per cent. economy over the best steam practice of to-day. Nevertheless, the gas-engine was undoubtedly coming on, and there were conditions where the engineer would be justified in using the gas-engine in conjunction with steam plant where there was sufficient overload power in the turbine or engine to carry over a breakdown.

Mr. W. H. BOOTH said there were several hundred horse-power of good, reliable gas-engines working in Germany, and yet in this country we were discussing whether the big gas-engine would turn round.

Mr. J. B. ROBINSON (Richardson, Westgarth and Co.) said that the position of the British gas-engine builder had not been fairly and truly represented in the Paper, where it was stated that few gas-engines had been made in this country over 300 to 500 h.p. His firm had constructed some 800-h.p. engines as far back as 1903, and they were still running. Amongst those of later date were 10 1,000 h.p. engines, and there was no doubt that the British gas-engine builder was quite ready to make large engines as soon as the orders came along. With Mr. Schmer he was willing to take any number of orders for large gas-engines. He could not agree with the figures of capital cost put forward in the Paper, particularly for the steam-turbines. He would reduce the cost of turbines from £13 19s. per kw. to about £12 13s. with cooling towers, or £11 16s. without. The gas-engine prices were about correct; if anything, they were on the high side. With these corrections the gas plant would cost about 40 per cent. more than the steam plant with towers, or 32 per cent. more without towers. Under these conditions, the combination of gas-engines with steam-turbines was the right thing. He agreed substantially with the figures for repairs given in the Paper. At the Cockerill works, for the year ending March, 1907, they generated 24,000,000 units. The plant had a total capacity of 84,000 h.p., and with that output there was a load-factor of 50 per cent. The works costs came out to 0·062d. per unit, and it was pointed out that if the load-factor were reduced to 25 per cent., the costs would be increased to 0·116d. per unit. Figures for load-factors of 75 per cent. and 100 per cent. showed that the costs were practically the same at all outputs. Therefore, if they were able to take a higher load-factor than that in the Paper, the advantage of the gas-engine showed enormously in this respect. Even at the low load-factor and with the corrections he had made in capital cost, there was considerable advantage. The figure deduced for labour, viz., engine attendance, generator and switchboard attendance, and general superintendence for the above plant at 24 per cent. load-factor, was 0·056d. against 0·041d. in the Paper, and for repairs, 0·051d. against 0·052d. in the Paper. This showed that the authors' figure of £4,000 for repairs was a fair one, and had already been carried out in practice. The authors' figure for oil was rather low—namely, 0·015d. against 0·023d., so that, on the whole, these figures would require to be increased by about 10 per cent. for the works costs. These corrections would bring the total costs for the gas plant to 0·39d. per unit, and, by reducing the capital charges on steam-plant, the total costs were brought down to 0·462d., so that even on the light load-factor of 24 per cent., the gas-engine justified its installation. To deal with the minimum load with 80 per cent. or 90 per cent. load-factor, there was no question whatever that the gas-engine was the right thing to put in.

Mr. B. STEWART (Beardmore & Co., Glasgow) also thought that the capital cost of gas-engines as given in the Paper was too high. He was inclined to think that too much importance was being attached to the question of dirty gas. He thought that the cost of repairs had been overstated in the Paper. During 1908 a 1,500-h.p. single-cylinder gas-engine, driving a rolling mill at one of his firm's works, cost, including two half-yearly general overhauls, £119 9s. 5d. on wages and material. A 500-h.p. engine in the same works cost £91 10s. 6d. in repairs. Regarding the limit of power which the authors put upon a single sylinder, he said that he had experienced no trouble from a 1,500-h.p. engine, which had a cylinder of 43⅜ in. in diameter, and he did not think they had yet reached the limit in this direction. The price of coal was a purely local condition, although with their ammonia recovery plants his firm had been using some very low-class fuel, in a plant which aggregated 100,000 h.p. In Scotland they bought a very cheap bituminous coal at 7s. 1½d. per ton delivered at the works. This was used in an ammonia recovery plant, and the amount of ammonia sulphate recovered during a year's working averaged 84 lb. per ton. It appeared to be entirely forgotten that most of the gas-engines in Germany had the advantage of being connected with works that had blast furnaces. That was very seldom the case here, and, consequently, we had been compelled to put in producer plants. He associated himself with the opinion that a combination of steam-engines and gas-engines was suitable for power-stations.

Mr. W. DIXON (Gas Power Co.) thought that many of the troubles experienced in England with gas-engines were due to an endeavour to utilise German experience, overlooking the fact that this experience had been gained largely with blast-furnaces and coke-oven gases. Probably the most important suggestion in the discussion was that of combining steam-engines with gas-engines, and if a station was large enough to warrant an ammonia recovery plant which could be kept fairly well employed, this would go a long way towards cancelling the coal bill. It was not only in one part of the country that it was possible to get coal for 7s. per ton which would give 7s. worth of sulphate of ammonia per ton. In practically all districts, coal could be obtained at from 7s. to 10s. per ton, which would be serviceable in ammonia recovery plant, and leave a margin of 2s. or 3s. above the actual cost of the coal.

Mr. W. HANDCOCK (Messrs. Handcock & Dykes) gave some figures relating to a gas-engine station with a capacity of 150 kw., running with a very bad low factor, and using fuel at 16s. per ton. The works costs came out at 0·25d. per h.p. hour, and about 0·03d. for lubrication. They would have to go a very long way to get figures anywhere near these for steam plant. Another point to be emphasised was the very great value of gas-power in districts where fuel was fairly expensive, for industrial works which had long working hours. Taking, for example, a works having about 750 kw. of plant, running 140 hr. per week for 50 weeks in the year, and using coal at 12s. per ton, and comparing the average turbine figures with gas figures, the total in favour of gas at the end of the year was about £3,000, or £3 per kw., which would allow the payment of a very respectable dividend.

Mr. LEONARD ANDREWS replied briefly to the discussion, as the authors are reserving their full reply for a communication to the *Journal*.

Mr. P. O. MIOSKOWSKI (Augsburg-Nurnberg Maschinenfabrik), in a written communication, stated that he had, during the last few years, had charge of about 50 large Nurnberg gas-engines ranging from 600 B.H.P. to 3,200 B.H.P., and had access to figures relating to over 200 double-acting engines built by his firm during the last six years. The authors gave the figure of £4,000 as the total costs of up-keep and repairs for the whole gas-plant; of this, those relating to the producer and ammonia plant may be estimated at £500, and those for the buildings £300, so that £3,200 remains for the engines and alternators. This figure, he thought, would be reduced by one-half with carefully attended modern gas-engines. With a total cost of £1,600, the cost per unit would be 0·0183d., and he was prepared to substantiate this figure from actual running costs. The average figure taken from the reports of his company, with Nurnberg gas-engines all running with about the same load-factor, was 0·00851d. per unit. Finally, Mr. Mioskowski thought the figure of £970 for oil rather high; in his experience, 0·24 gallons per 1,000 B.H.P.-hour, inclusive of the lubrication of compressors and pumps, was ample. Taking this figure instead of the authors' 0·37 gallons, the total cost would be about £650.

An Italian Electrical Exhibition.—Copies of the programme and regulations of the international electrical exhibition to be held at Brescia this year have, says the *Board of Trade Journal*, been received at the Board of Trade, and may be obtained by British firms applying either at the Commercial Intelligence Branch, 73 Basinghall Street, London, E.C., or at the Exhibitions Branch, 32 Great George Street, Westminster, S.W.

Lantern Slides of Electrical Plant.—Messrs. Siemens Brothers' Dynamo Works, Ltd., of Caxton House, have sent us a list of over sixty lantern slides illustrating interesting examples of electrical plant, &c., of their manufacture, ranging from complete power and traction equipments to small supplies, which they are prepared to send to lecturers free of charge.

Post Office Engineers' Annual Dinner.—The sixth annual dinner of the Post Office Engineering Department was held at the Grand Hotel on Tuesday, February 16th, Major O'Meara, C.M.G., Engineer-in-Chief, presiding, and the guests included a number of well-known electrical engineers. The Postmaster-General, in his speech, proposing the toast of "The Engineering Department," referred to the progress which the department has made during the first year of office of Major O'Meara, and mentioned the opening of the Bolt Head wireless telegraph station and the extensive additions to the underground system made during the year. He welcomed Mr. Gill, as representing the National Telephone Co., and looked forward to the time when they would be taking over that undertaking, including perhaps Mr. Gill himself. Major O'Meara, in responding, read a letter from Sir William Preece, regretting his inability to attend on account of a chill, and referred to the success of the Buda-Pesth Conference, which he had attended. The toast of "The Visitors" was proposed by Mr. Catley and replied to by Sir Henry Babington Smith, Secretary to the Post Office, and Mr. W. M. Mordey, President of the Institution of Electrical Engineers, and, finally, Mr. I. Probert proposed the health of the Chairman, to which Major O'Meara briefly responded.

THE MANCHESTER LOCAL SECTION DINNER

Mr. Ferranti on the Lowest Tender

AT the annual dinner of the Manchester Local Section of the Institution of Electrical Engineers, last Friday, Mr. S. Z. de Ferranti, in proposing the toast of the Corporations of Manchester and Salford, said that, personally, he did not believe in municipal trading at all, but since they were allowed to trade, municipalities should be allowed to do it well and should be given a free hand. It was an evil thing that the electrical industry had been brought up on the basis of the lowest tender. There was, he said, no longer any such thing as "goodwill" in the electrical industry in this country, for a municipal engineer did not dare to place an order with a firm with whose plant he was satisfied if that firm's tender was not the lowest. No trading could be successful with such unlimited competition. As an instance, he mentioned the London Electric Supply Corporation's scheme of twenty-one years ago. Although he had put it down on the lines now recognised as the correct ones, it had been a failure because seven competitors had been created by Parliament in the same area. Another effect of the system of competitive tenders was that there was no margin of profit left for experimental work. Mr. Ferranti concluded with a hint that electrical manufacturers should combine to protect themselves against this system.

The Mayor of Salford, who was in the chair, responded to the toast.

Mr. W. M. Mordey, replying to the toast of the Institution of Electrical Engineers (proposed by Col. H. T. Crook, Chairman of the Manchester Section of the Institution of Civil Engineers), gave some of the statistics that the proposer of the former toast should have furnished according to custom. He said that the Manchester Electricity Department sold 82 B.T.U. per inhabitant per year, which was more than any other town in the United Kingdom, at an average price of 1·51d. per unit, or, leaving out lighting, the average price of power was only just over ¾d. per unit. Coming next to the affairs of the Institution itself, he said that, thanks to the co-operation of the Local Sections, the new method of dealing with Papers was succeeding well. As to the new building, the Institution need have no fear on the score of expense, as arrangements had been practically completed for the letting of some of the extra rooms to other societies. He refused to accept the pessimistic views that are being expressed as to the present state of the electrical industry; he had held for years that the supply of electrical engineers was greater than the demand. The effect of this was, he said, that there was a falling-off in the attendance of students at classes, and it would adjust itself. If it were not for the pressure of over-population and unemployment, he concluded, we should not be the colonising country that we are. Mr. Miles Walker, Chairman of the Section, replied.

Mr. F. Gill (Engineer-in-Chief of the National Telephone Company), in drinking to the health of the visitors, recalled the fact that the Manchester Section had originally been an independent society, the Northern Society of Electrical Engineers, and that since it became wedded to the Institution it had greatly increased in strength. The membership was now about 800, and it was the only one of the Local Sections that had a students' section of its own. The toast was acknowledged by Prof. E. Rutherford.

Telephone Charges.—The Committee of the Associated Chambers of Commerce, reporting upon their negotiations with the National Telephone Co. with regard to the new telephone charges, state that these have been a complete failure; the Telephone Company had taken the matter into their own hands, and nothing could be got out of them.

Imperial International Exhibition, Shepherd's Bush.—An influential committee has been formed for the purpose of organising a British electrical section at the forthcoming exhibition to be opened early in May on the site of last year's Franco-British Exhibition. Mr. F. J. Walker is chairman of the committee, which also comprises the following gentlemen: Mr. H. W. Bowden, Mr. A. F. Berry, Mr. H. Hirst, Mr. Leonard Holmes, Mr. C. O. Grimshaw, Mr. H. W. Miller, Mr. T. W. Wallis, Mr. J. C. Dyas, Mr. C. Wilson, Mr. A. T. Turney, Mr. C. S. Leach, and Mr. F. B. Converse (*Hon. Sec.*) We understand that space has already been applied for by representatives of the American, German, and Swiss electrical industries, and it is hoped that this country may be thoroughly well represented. In the Machinery Hall a space of about 10,000 sq. ft. has been offered by the Exhibition authorities for prompt acceptance, and an additional space equivalent to one-third of this amount has been kindly promised free of all rental charges by the Exhibition authorities for the Historical, Educational, and Scientific Sections only. The Committee has also favourably considered the suggestion to erect and equip a large electrical village, instructive and interesting to the various sections of the public, on a space adjoining the British electrical exhibits, and next to the Machinery Hall. It is proposed that the village enterprise should be undertaken by an existing organisation under the control of the committee, and negotiations to that end are proceeding.

CATALOGUES AND PAMPHLETS RECEIVED

[READERS APPLYING TO ANY OF THE UNDER-MENTIONED FIRMS FOR COPIES OF THE CATALOGUES OR PAMPHLETS REFERRED TO ARE REQUESTED TO MENTION "ELECTRICAL ENGINEERING."]

SWITCHES.—A new pattern of high-voltage double-pole turn switch is illustrated in a leaflet issued by the Electric & Ordnance Accessories Co., Ltd., of Birmingham. These switches are made in three sizes for 15, 25, and 50 amperes for circuits up to 500 volts. They are entirely without fibre parts, and have a quick, long, double break and adjustable contacts, making them very suitable for arc lamp, fan, or heater circuits.

TIME SWITCHES.—Messrs. Venner & Co., of 6 Old Queen Street, Westminster, have issued a new section of their time-switch catalogue, in which are described a number of ingenious selective devices, which greatly extend the utility of the Venner time-switch system, and enable a different cycle of operations to be carried out on selected days of the week.

CALENDAR.—We have received from the Campbell Gas Engine Co., of Halifax, a daily tear-off wall calendar from March, 1909, to March, 1910. An illustration is given thereon of one of the firm's single-cylinder horizontal gas engines.

HYDRAULIC LIFTS.—Messrs. R. Waygood & Co., Ltd., have sent us a copy of the new edition of their catalogue of hydraulic lifts, covering a very wide range of this class of engineering. Among the illustrations is one representing a 15-ton lift in use by the City & South London Railway for bringing passenger coaches to the surface.

THREE-PHASE MOTORS.—The latest lists of Oerlikon manufactures issued by Mr. G. Wütrich, of 43 Norfolk Street, W.C., deal with the three-phase slip-ring induction motors up to 85 h.p. for voltages up to 500 volts 50 cycles.

FITTINGS.—We have received from Messrs. Siemens Brothers Dynamo Works, Ltd., who are now opening a fittings' department at 6 Bath Street, City Road, a copy of their new 84-page fittings' catalogue. A large number of fittings specially designed for use with tantalum lamps are included, among which is a very complete series of "holophane" shades, reflectors, &c. Other special fittings comprise a group of majolica porcelain single-light ceiling and wall fittings, a large variety of "Solar" fittings for "tantalum sun" lamps, and watertight exterior fittings for street lighting and other purposes.

Ventilation of Collieries.—We learn from Messrs. Davidson & Co., of Belfast, that a large number of the principal mines in South Wales are adopting the Sirocco Fan for ventilating purposes, among them being the group comprising the Cambrian, Glamorgan, and Naval Collieries, the underground roadways of which aggregate about 130 miles. At the Cambrian the fan is to be a double inlet Sirocco, 14 ft. in diameter, capable of exhausting the enormous volume of three-quarters of a million cubic feet of air per minute. It will be driven by a 2,000-h.p. engine. The fan at the Naval Colliery will also be of the double inlet type, measuring 10 ft. 6 in. in diameter, with a capacity of 400,000 cubic feet per minute. The third fan of the group, that of the Glamorgan Coal Co., has been in operation for some months, and at a recent official test showed a fan efficiency of over 80 per cent. This fan is a doublet inlet Sirocco, 11 ft. 8 in. in diameter, and has a capacity of 340,000 cubic feet per minute. The same type of fan has also been adopted by neighbouring collieries, such as Ferndale (D. Davis & Sons) (ELECTRICAL ENGINEERING, Vol. IV., p. 209), where the three fans installed show exceptionally high efficiencies. Among other Welsh collieries, Sirocco fans are also being installed at the Atlantic Merthyr Colliery, and the Penallta Pit of the Powell Duffryn Co., the latter being 12 ft. 10 in. in diameter, and designed for a duty of 500,000 cubic feet per minute.
